If one or more bystander positions are defined, the A-Weighted sound pressure level shall be measured for the operating mode(s) and idle mode defined in Sec.5. Section 7.3.2.1 and Fig. 2 of ANSI S1.13-1971(R1976) may be used as guide to define bystander position around the machine. The measurements shall be carried out in accordance with the procedures of ISO DIS 6081.

LaserWriter ROMs: PostScript Versions Explained

I have some technical questions about different versions of PostScript:

1) I thought that LaserWriter ROM versions 1.0, 2.0, and 3.0 correspond to versions 23, 38, and 47 of PostScript. However, in LaserWriter Plus printers the ROM contains 42.2. What happened to 47.0?

2) Also, when extracting information from a printer, CE Software's Widgets reports version 47.0 (1) for a LaserWriter IINT and a LaserWriter IINT which was upgraded to a LaserWriter IINTX. It also reports 51.8 (3) for a LaserWriter IINTX. What do the numbers in parentheses really stand for?

3) What is the difference between 47.0 and 51.8?

Adobe Technical Support said that these versions are functionally identical, which doesn't really answer my question.

This article has been archived and is no longer updated by Apple.
1) There is a an error in the LaserWriter Plus ROMs that gives the version number 42.2 if read from PostScript, even though the ROMs contain Version 47 of PostScript.

PostScript version 47 is different than PostScript version 38 in the following ways:

* It is slightly faster.

* It contained miscellaneous bug fixes.

* It added code to support SCSI hard disks (as in the LaserWriter IINTX).

The Rev 47, PostScript-code-equipped LaserWriters can function up to 25 percent faster when printing text or up to 40 percent faster printing bit-mapped graphics. PostScript version 38 is functionally equivalent to PostScript version 47 except for the above details.

2) CE Software's Widgets 3.0.4 issues two PostScript commands to get the "51.8(3)" from the LaserWriter IINTX with the latest ROMs. The first is the "version" command. This command returns a string that identifies the version of the PostScript language and interpreter being used. The second is the "revision" command. This command returns an integer designating the current revision level of the machine-dependent portion of the PostScript interpreter.

3) PostScript version 51.8 allows for the following enhancements:

* The entire font list is no longer searched when looing for a font. The search stops as soon as the font is found. This can save a lot of time if there is a hard disk attached and the font is a ROM font.

* Full support of software switching between emulations and ports. It is now possible to both switch into and out of an emulation mode via software.

* Improved support of multiple SCSI disks. You can now connect up to 8 SCSI hard disk drives to the LaserWriter IINTX SCSI port. Up to 80 percent of the hard disk with the lowest SCSI ID is used for font caching with the remainder of that disk and all of any other connected

hard disks used for downloaded fonts. Each hard disk is now formatted as a separate volume, which lets a user move a disk (other than the startup disk) between systems without needing to reformat.

* Additional characters in the HP Laser Jet+ emulation. Four characters have been added that had been left out of the original implementation of HP Laser Jet+ emulation.

* Improved default settings for HP Laser Jet+ bit map printing. Previously, bitmaps in HP Laser Jet+ mode were interpreted at 7-bit, thus ignoring a significant bit. The new ROMs default to 8-bit serial communications.

Note: These new ROMs are in all LaserWriter IINTX printers with a part number ending in 6004/A.

HyperCard 2.0: LaserWriter Driver 5.2 Print Problem (11/94)

I have been trying to resolve a HyperCard 2.0 printing problem. My system includes System 6.0.5, Finder 6.1.5, LaserWriter Version 5.2, AppleTalk driver version 53, and no INITs.

I'm unable to print cards from a stack that I have developed. When I try to "Print Card" from the File menu, I get a message "Processing Job" that stays on the screen indefinitely. The printer still thinks it is connected to this job, even after I cancel printing, so I have to restart the printer.

Oddly enough, this stack does print to a QMS PS2200 Laser Printer.

This article has been archived and is no longer updated by Apple.
We were able to reproduce the problem with the stack you sent. However, using LaserWriter driver version 6.x the card printed fine. Try upgrading to newer drivers; that may well solve the problem.

DeskWriter Printer & Macintosh: Service Notice from Apple, H-P

This article contains an Apple Service Notice and its Hewlett-Packard counterpart sent out to Hewlett-Packard service providers on November 1, 1990.

This article has been archived and is no longer updated by Apple.

APPLE SERVICE NOTICE

Some Macintosh Serial Ports Affect Hewlett-Packard DeskWriter Printer Operation

Overview

==========

It has come to Apple's attention that some customers have been experiencing print problems when using a Hewlett-Packard DeskWriter printer and a Macintosh computer. Typically, the customer has purchased the computer and the printer at the same time. The customer connects the DeskWriter to the Macintosh printer port and configures the printer for serial mode. Usually the system works properly for several weeks or even several months; suddenly the printer will not print the selected text. When the DeskWriter will not print the selected text, the printer lights will flash, and the printer sometimes prints "Error Trap 10864".

If the cable is moved from the Macintosh printer port to the modem port, the DeskWriter prints properly; however, it may fail in a similar manner after a few weeks of use.

It is important to note that the Macintosh printer port may still be operational and may pass a diagnostic test or work normally with other print devices.

Customers have reported this when using a Macintosh II, Macintosh IIci, Macintosh IIcx, Macintosh IIfx, or Macintosh SE computer. The problem appears to be limited to a small number of these systems.

Solution

==========

Both Apple and Hewlett-Packard have conducted separate investigations and have isolated the cause to a component failure on the Macintosh logic board. When this failure occurs the sensing circuit in the DeskWriter causes the printer to switch to AppleTalk mode, thereby prohibiting further communication with the computer in serial mode.

To correct the problem Service Providers should replace the logic board on the Macintosh system. Systems within the warranty or AppleCare period should be repaired under these programs. For systems outside the warranty or AppleCare period contact Technical Operations for further instructions.

HEWLETT-PACKARD ANNOUNCEMENT

Some Macintosh Serial Ports Affect DeskWriter Printer Operation

For the past few months, Hewlett-Packard has been receiving a small number of customer reports that DeskWriter printers won't print on Macintosh computers. Typically, the customer has purchased both computer and printer at the same time. The customer connects the DeskWriter to the Macintoshes Printer port and configures it for serial mode. The system works properly for a few weeks or even a few months; then the printer does not print the selected text. The DeskWriter's lights flash, and the printer sometimes prints "Error Trap 10864." If the cable is moved to the Macintoshes Modem port, the DeskWriter works properly; however, it may fail in a similar manner after a few weeks have passed. This has occurred on Macintosh II, Macintosh IIci, Macintosh IIcx, Macintosh IIfx, and Macintosh SE computers.

Both Apple and Hewlett-Packard have conducted separate investigations and have isolated the cause to a component failure on the Macintosh logic board. We have determined that on a small number of Macintosh computers the resistances of the I/O lines degrade over time and eventually fall below the RS-422 specification. When this occurs, the sensing circuit in the DeskWriter causes the printer to switch to AppleTalk mode, thereby prohibiting further communication with the computer in serial mode.

It is important to note that the Macintoshes Printer Port may still be operational and may pass a diagnostic test or work normally with some other print devices. Hewlett-Packard's and Apple's joint recommendation is that any DeskWriter user who experiences this problem should return the Macintosh to an Apple- authorized service provider for repair, according to Apple's recommended procedures.

Apple will soon be issuing a statement (Apple's Statement is above) that further describes this problem, along with their technical recommendations. Until that time, service providers should contact their Apple Service Representative for instructions. In closing, Hewlett-

Packard would like to thank Apple for their cooperation and prompt response in this matter and express our regret for the inconvenience this has caused our mutual customers.

IMPORTANT NOTES (5/95)

This problem is limited to the Macintosh models listed above. If you have another model other than the one's listed above, your problem is not necessarily a hardware failure. In most cases, when you get an error message generated by the DeskWriter software mentioning that the serial port is in use, it is caused by using the serial DeskWriter printer driver, and having AppleTalk turned on.

In order to print using the serial DeskWriter printer driver, you must have AppleTalk turned off. If you need to use AppleTalk, use the AppleTalk DeskWriter printer driver.

AppleShare PC and Memory Allocation

I am using AppleShare PC and when I "convert printer" (F2), the memory is not being allocated. I'm running a PS/2 with DOS 3.3 and a Digital DayStar LT200 LocalTalk card.

This article has been archived and is no longer updated by Apple.
It sounds like you need to increase the AppleShare PC memory pool. At boot time, AppleShare PC sets aside an amount of memory for protocol stacks and connections to file and print servers. Each printer connection consumes 7K, so it is easy to exceed the default memory-pool size if you make more than one connection.

The amount of memory that AppleShare PC allocates is defined in the NET.CFG file, generally located in the directory with the other AppleShare PC files. The important line will be near the top of the file and should look something like this:

MEMPOOL 23K

Use EDLIN, or (preferably) a text editor you like, to increase the number. First, try making it 7K larger than its current setting. Save the changed file and reboot. The extra memory allocated should let you make the printer connection. Note that this additional memory will be taken from your available conventional memory, so it should not be larger than needed.

You may want to make sure you're not making unnecessary connections to printers that aren't being used. A leftover automatic connection may be using up your default memory pool when you don't need it. If possible, use the DA to "Review Auto-Connections" and remove those you don't use.

Published Date: Feb 18, 2012

AppleShare PC and Zone Limits

Does AppleShare PC have a 100-zone limit?

This article has been archived and is no longer updated by Apple.
AppleShare PC's only limit with respect to the number of zones it can work with involves the memory available in its memory pool when DA is run. This only affects making network connections using DA, and has no effect once those connections are made. Even then, the connections could still be made using manual ANET commands, even with thousands of zones. We use default installations of AppleShare PC here at Apple, where there are over 140 zones, and have no trouble using DA to make connections.

Problems can occur if the AppleShare PC memory pool is almost full. This is the memory that AppleShare PC allocates at startup and is configurable by changing the MEMPOOL setting in the NET.CFG file. If you are experiencing the "Not Enough Memory" message, increase this number by 1 or 2K and the problem should be eliminated. Because the NET.CFG file is read when AppleShare PC loads, the user must edit the file and then reboot the PC before the change can take effect.

Current versions of AppleShare PC actually require Phase 2 networks. This is frequently a problem when people upgrade from an old version (pre 2.0) and haven't upgraded all their services to be Phase-2-compliant. The AppleShare PC node cannot see Phase 1 services like AppleShare File servers running EtherTalk 1.x.

MacX25: Problem Reports and Enhancement Request

We've noted the following problems with MacX25:

1) To use MacPAD, MacTerminal needs more than 512K of RAM free.

2) If you have a session open, and have disabled the PAD command mode, typing a Control-P seems to indicate that your session is closed, yet the MacPAD status still shows you as connected. Nothing could be found that would let the session be re-used again without doing an Open Connection.

3) MacX25 apparently cannot insert a calling address. At least, we can't find any option for this setting. We had to patch our network to make this work, as we validate the calling nua before the call is directed to its destination. We need the ability to trace a call for accounting purposes and for troubleshooting problems.

Its implementation should be based on the user ID and assigning each user an nua or sub-address (i.e., unique address). The sub-address would be easier to maintain, because the administrator would have to type only two digits instead of the whole nua. When using the sub-address scheme, the server would be assigned an nua like 10498001%%, where %% is replaced by the sub-address from the user ID.

4) MacTerminal seems to hang quite frequently, at least on a Macintosh IIci, when trying to change the PAD command mode while a connection is open (actually a "stuck" connection as described in question 2).

5) The installation of MacTerminal puts an INIT in the System file that seems incompatible with other INITs, namely with INITPicker (when using override). This INIT should be a separate file from the System file, so the user can control when and if the INIT should run.
This article has been archived and is no longer updated by Apple.
1) The minimum suggested memory size for MacPAD (MacTerminal or CommToolBox) is 1MB, though 2MB is recommended. The MultiFinder "Suggested Memory Size" is 560K for MacTerminal itself.

2) Questions 2 and 4 are related:

The "MacX25 User's Manual" (page 110) suggests you can go into the PAD command mode by entering Control-P. That means if you checked "enabled PAD command mode" (see "Connection Settings" on page 97), you can escape from data transfer (page 99), then enter any of your CCITT PAD commands from the keyboard. When you have checked "enabled MacPAD command mode", you can "escape" into MacPAD command mode by entering Control-P or by choosing Command Mode from the MacPAD menu.

However, if you have NOT checked "enable MacPAD command mode", you cannot enter a PAD command mode with the Escape key sequence or menu to escape to data transfer mode after starting a session. The host will interpret anything you enter through the keyboard as data. If you try to escape to command mode with a Control-P (Command Mode in the MacPAD menu is not available), the system may appear to hang. If you check Status in the MacPAD menu, it will show that you still have a live session. If you are patient, some hosts will time out (the ones we tested did so after 1 minute) and resume the data transfer.

During this time, the session menu gives you the option to open a connection, but doing so will hang your system. If your host never times you out, we recommend you quit MacTerminal, reboot, and restart your session.

3) We passed this enhancement request along. Thanks.

4) See the second item above.

5) We haven't had any conflicts with INITPicker 2.0 (or other INITs) and the INIT that the Communications Toolbox installs into the System file. We have used this combination on various systems including a Macintosh Portable, Macintosh IIci, Macintosh IIcx, and Macintosh IIx, running various versions of System Software including 6.0.4, 6.0.5, and 6.0.7. It is true, however, that INITPicker 2.0 cannot control the state of the INIT when it is installed in the System Folder. However, it is one less variable a user must monitor to conduct a successful communication session.

LaserWriter: How to Print Diacriticals

This article has been archived and is no longer updated by Apple.

There is a way to use the LaserWriter fonts' diacritical marks, the curved short-vowel symbol (shift-option-period) and the straight long-vowel symbol (shift-option-comma). A/UX: YP and MacTCP Tool Problem (9/94)

I am using A/UX with Yellow Pages in an all-Sun environment to maintain my home directory on a remote Sun server. When I launch MacX, I get the message that "Connection Tool Cannot be Found". Thinking that the connection tool needs to be in the Extensions Folder within the Macintosh System Folder on the Home directory (on the remote Sun server), I ran "Systemfolder" from the command line. Upon logging off and back on, I was unable to complete the YPbind process.

I conclude that Macintosh System Folders are illegal on a Sun file system, or that YPbind cannot reconcile the Macintosh system resources with the home directory. In any case, I cannot think of any way to have MacX use the communications tool (MacTCP) from Root, or from any other local users.

This article has been archived and is no longer updated by Apple.
When executing a "systemfolder" command to create a personal System Folder under the user's home directory, it creates a "System Folder" under the user's home directory, copies files from /mac/lib/SystemFiles directory but not from the default /mac/sys/'System Folder' directory. The communication tools, which were stored in the /mac/sys/'System Folder'/Extensions directory, are not copied to the user's newly-created Extensions folder.

For users with their home directory on the remote YP and/or NFS server to launch MacX successfully, the MacTCP Tool must be manually copied into their own Communication Folder under the user's $home/'System Folder' directory. Otherwise, MacX complains with the following message:

An unexpected error has occurred: The Macintosh Communication Toolbox
could not be initialized because there are no communication tools
installed.

We have tested launching MacX in one A/UX without any problem from an account whose home directory resides (via nfs mount) in another A/UX YP and NFS server. We do not think there is a problem between Macintosh System Folders and Sun YP and NFS file system.

Regarding being unable to complete the YPbind process, was there any message indicating that you were unable to complete the YPbind process? Was the YPserv (YP server) running before YPbind (YP client) was started? We do not think that your problem (launching MacX) has anything to do with the YPbind or YPserver, unless the YP server and client were not up and running.

Try to copy the MacTCP Tool manually into the user's System Folder/Extensions folder, logout and login, then launch MacX again.

HyperCard 2.0: Using HyperDialer

I have a stack that was designed to use the HyperDialer as part of our office mail system. I recently began using HyperCard 2.0 and found that when HyperCard dials the tones to the speaker, they are either too fast or corrupted. This causes the dialing procedure to fail.

Is there a reason for this? If so, are there provisions in HyperCard 2.0 for greater control over dialing through the speaker?
This article has been archived and is no longer updated by Apple.
DataDesk International, manufacturer of HyperDialer, was unaware of any inconsistencies between HyperCard 2.0 and their product. They did say that if the numbers are dialed too quickly, the phone system will interpret them as trash and not dial appropriately.

While there are no new controls for HyperCard's "dial" command, we found that dialing each number in a separate command caused approximately a 10 percent delay in the dialed string.

Fast	10% Slower
on mouseUp dial "1234567890" end mouseUp	on mouseUp dial "1" dial "2" dial "3" dial "4" dial "5" dial "6" dial "7" dial "8" dial "9" dial "0" end mouseUp

You can further slow the dialed string by placing commas or semicolons between the numbers. A comma causes a one-second pause; a semicolon results in a ten-second pause.

```
on mouseUp
dial "1,2,3,4,5,6,7,8,9,0"
end mouseUp
```

Personal LaserWriter: Printing Envelopes

Article Change History

02/12/93 - REVIEWED
* Vendor information.

I'm trying to print envelopes with IJ Personal LaserWriter, but can't get a clean feed when using envelopes.

This article has been archived and is no longer updated by Apple.
The Personal LaserWriter models have a somewhat more complex paper path than that of the LaserWriter II models. We have heard reports of problems with some envelopes, especially those made from a heavy stock.

Handling can be improved by using envelopes that are approved for use in laser printers and copiers, and by feeding to the face-up delivery tray. The recommended envelopes are No. 10 (standard business envelopes) or those specially made to withstand use in laser printers and copiers. Two manufacturers of such envelopes are James River Corporation (Groveton Division) and Avery. Check with your local office supply dealer or with the manufacturer.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

LaserWriter IINTX: RAM Allocation

How much RAM is needed to get a second page buffer with legal-size paper on LaserWriter IINTX?

This article has been archived and is no longer updated by Apple.
Additional RAM does not provide space for a "second page buffer" in the LaserWriter IINTX. We found the following information on page 122 of the "LaserWriter IINT/NTX Owner's Guide" (ROM revision 3.0 version):

Memory Upgrades

You can install up to 12MB of RAM in the LaserWriter IINTX. You can also add a font expansion card. These memory upgrades are not possible on the LaserWriter IINT.

RAM upgrades for the LaserWriter IINTX provide the following benefits:

* the ability to print very complex documents (graphics and CAD documents, for example) that might not print on printers with less memory

* faster performance on complex documents

* faster performance when using downloaded fonts

* faster performance when printing documents that have been scaled down from larger originals (organization charts, maps, flow charts, for example)

* The ability to increase the imageable area of a document (you can use more of a sheet of legal paper, for example)

Adding more RAM provides these benefits in three ways:

* More RAM allows more fonts to be downloaded (sent over the network) to the printer at any one time. The printer is less likely to need to retrieve large font files over busy network cables, saving you time and improving the performance of the entire network.

* More RAM increases the space available for font caching. Before the LaserWriter IINTX can print, it converts the PostScript outline fonts into bitmaps, which it stores (caches) in RAM. When the demand for RAM exceeds the supply, the printer discards the less recently used bitmaps in favor of the newer ones. When the discarded bitmaps are needed again, the printer must rebuild them. With additional RAM, the printer will need to rebuild bitmaps less often.

* Finally, more RAM gives your printer more space to store the calculations it uses to compute large or complex page layouts. This is why you can print more complex documents and use a larger imageable area when you install more RAM.

A/UX: Installing/Deinstalling AppleTalk (9/94)

Article Last Reviewed: 8 September 1994

I have a problem with AppleTalk on A/UX:

1) AppleTalk is installed, and if I choose a LaserWriter in the Chooser, all is okay.

2) If I de-install AppleTalk with "newconfig appletalk" and then reboot, at the login dialog box, a message appears several times indicating that the system cannot find the LaserWriter I recently chose.

Is there anything else needed to de-install AppleTalk?

This article has been archived and is no longer updated by Apple.
The following are notes for installing and/or de-installing AppleTalk on A/UX:

* The "appletalk" module is configured with the standard A/UX kernel. You don't have to actually do "newconfig appletalk" in the first place. However, if you suspect that some modules of AppleTalk might be corrupted for some reason, you may de-install AppleTalk by doing "newconfig noappletalk", then re-install it by doing "newconfig appletalk".

* You may choose either EtherTalk or LocalTalk for printing on an AppleTalk network. This is controlled by the /etc/appletalkrc file with a line indicating which interface is used. For instance, to use LocalTalk, the following line needs to be specified:

interface = localtalk0

* The default LocalTalk printing port is the printer port (/dev/tty1). This port must be set to getty "off" in the /etc/inittab file.

* The following commands should be initiated whenever the interface is changed:

appletalk -d # bring AppleTalk down
modify the /etc/appletalkrc # choose AppleTalk interface
appletalk -u # bring AppleTalk up

* The "appletalk -s" command is useful to see if the AppleTalk interface is active, and to display LAP and DDP statistics.

* You may use "Chooser" from the Apple menu or use the "at_cho_prn" command from A/UX CommandShell window to choose your favorite printer.

* Two printer spoolers, Berkeley printer spooler (lpd) and AT&T System V printer spooler (lp), are available under A/UX. The default is "lpd".

For more information, refer to Chapter 3 "Connecting to an AppleTalk Network" in the A/UX Network System Administration documentation.

For the error messages appearing on the Login Dialog, you might check if both LaserWriter and Laser Prep are installed in A/UX or the Personal System Folder, and if it is compatible with the one currently used by that LaserWriter.

MacX and Extended Keyboard Mapping (5/95)

Can you give me some information about MacX and extended keyboard mapping?

This article has been archived and is no longer updated by Apple.
Unfortunately, there is no information on extended keyboard mapping in the "MacX User's Guide." However, according to MacX engineering, the PATHWORKS "MacX User's Guide" shows such a map in Chapter 1, Section "Mouse and Keyboard Differences". For example, the "Page Up" key is used to scroll to the beginning of a text field or to the top of a list.

Also, the user can use "xev", an X11 client to print contents of X events, to determine the keyboard mapping. "xev" is normally found in X11 client distribution. It is available in A/UX X11 Window System. The "xev" program creates a window and then asks the X server to send "events" whenever anything happens to the window. Events may include move, resize window, mouse clicked in, and keyboard typed in, and so forth. These reports can be displayed from the "Command Output" menu of the "Remote" menu in MacX.

Macintosh II: Video Overview (2 of 3)

This is the second part of a three-part article describing how the Macintosh II produces video.
This article has been archived and is no longer updated by Apple.

STANDARD RGB DISPLAY SIGNAL

The Macintosh II Video Card uses an approximation of the RS343 display signal. (RS video standards are set by the Electronic Industries Association.) The RS343 display standard is essentially a monochrome video signal combined with a composite sync signal (horizontal and vertical scan control) with timings that produce a non-interlace, or progressive, scan. This means that the horizontal and vertical scan rates are timed to cause the display electron guns to produce even progressively horizontal scans. This is by comparison to the interlaced video standards. The importance of the RS343 standard is its provision for a timing and voltage level signal that allows the display and generation of high resolution video.

While the Macintosh II version of the RS343 signal varies somewhat, it essentially follows the guidelines necessary for connection to RS343 display devices. The major differences are:

- the separate TTL level composite sync signal found on pin 3
- the separate video lines used to produce RGB color
- a vertical scan rate of 66.67Hz to reduce screen flicker
- a voltage white level of 1 volt for its red and blue signals and 1.3 volts on its green signal

RS343 provides for a 60hz signal but has been changed to 66.67Hz on the Macintosh II Video Card to prevent the screen flicker visible at 60Hz. The inclusion of the analog composite sync found on pin 5 of the video card connector, called the green signal, allows for monochrome composite video.

COMPONENTS OF AN NTSC/RS170 TIMING SIGNAL

RS170 is a standard that defines the timing of broadcast video in the United States, Japan, and several other markets. It specifies a 15.75KHz horizontal and a 60Hz vertical interlaced scan frequency. Interlacing is the process by which two fields, called scan lines, are interleaved on the screen. Due to the limitations of video devices at the time of the RS170 standard's creation in 1957, the speed of broadcast signals and picture tubes required the image to be displayed in part. The solution allowed for the partial update of video pictures to remain unnoticed to the viewer. An RS170 video frame contains 525 lines and is displayed 60 times per second -- for a total of 15,750 lines, or 15.75KHz. Of these lines, only the odd or even lines are displayed with each frame. A total of 60 frames per second allows for 30 frames per second, or 30Hz update of each line. Like the RS343 standard, RS170 is strictly a timing specification for monochrome video signals. By combining three such signals to control individual red, green, and blue sweep circuits, a full color system can be created. The RS170 mode was included on the Macintosh II video card as a way for large screen projectors, not capable of high frequency scans, to display the Macintosh II video in the usual broadcast standard of RS170.

THE MACINTOSH VIDEO CARD RS170 MODE

To produce RS170 video, software can be written to logically select the proper timing values and pixel clock from the Macintosh II video card. The pixel clock is a 12.2727MHz oscillator built on the video card and is selected over the 30.24MHz oscillator used in the RS343 mode. With the selection of the RS170 mode, a red, green, and blue signal with a separate TTL composite sync are produced. An analog composite sync pulse is superimposed on the green channel, allowing this signal to drive broadcast devices such as a television, to produce a monochrome image.

NTSC VIDEO (RS170A)

This is not available directly from the Macintosh II video card, but can be produced from the video signals supplied.

When color televisions became available, studios had to decide how to place color onto the broadcast bandwidths delivering black and white signals. There being very little space to work with, the solution was to use a color subcarrier signal modulated onto the luminance signal. The luminance signal controls the intensity of the black and white image. To place the color signal, or chrominance, onto the video signal, an NTSC color encoder is used. This effectively combines the primary additive colors red, green, and blue into a wave form. An output device filters the color signal from the luminance signal and recalculates the original values. To connect an NTSC color encoder, outputs for horizontal sync, vertical sync, blanking period, red, green, and blue in RS170 levels are required. These signals are all available on the Macintosh II video card and are discussed in the document "About Macintosh II Video Signals."

A/UX: AppleTalk Phase 2 and Ethernet Card Compatibility (8/94)

My group is having problems with third-party NuBus Ethernet cards and Phase 2 networks running on Macintosh II-class machines with A/UX 2.0. Is there a compatibility list of which cards support Phase 2 AppleTalk protocol? Is Apple's card fully compatible with EtherTalk 2.0 drivers using A/UX 2.0?

This article has been archived and is no longer updated by Apple.
We don't have a compatibility list of third-party Ethernet cards which support or don't support the AppleTalk Phase 2 protocols. Apple has left it to the developers to decide whether to write and implement a Phase 2 complaint driver for their cards. There is no conformity testing for third-party cards. This makes it difficult to compile a list of cards with known compatibility problems. We would suggest working closely with the manufacturer to ensure that any bugs in their drivers can be discovered and repaired.

The Apple Ethernet NB card is fully compatible with Phase 2 protocols when running under all versions of A/UX.

This article has been archived and is no longer updated by Apple.

It's been reported that the "unsupported status csCode: 8" error message is caused by applications that try to write a "SCRN 0" resource to the System file.

Further research reveals that the csCode: 8 is not included in the current supported control status code list (video.h) of the A/UX toolbox video driver. The following status codes are supported under A/UX 2.0:

```
#define cscGetMode 2
#define cscGetEntries 3
#define cscGetPages 4
#define cscGetBaseAddr 5
#define cscGetGray 6
#define cscGetVideoDefault 9
```

If any Macintosh application, like "After Dark 2.0", tries to use some video features not supported in the above list, it might have this problem too.

Note: After Dark is compatible with A/UX 3.0 because A/UX 3.0 supports the needed video calls.

AppleTalk Traffic When Launching Local Application

I have a problem for which I have no explanation. If I have one or more file server volumes mounted (but none of the directory windows are open), and I try to launch a local file with a local application, there is a delay of several seconds during which the AppleTalk traffic indicators blink.

This delay does not always occur and its occurrence does not appear to be tied to any specific condition on the Macintosh. I don't understand why there should be any AppleTalk traffic when launching a local application.

This article has been archived and is no longer updated by Apple.
Any time an application is launched, all of the information about any changes that have taken place on any currently-mounted volumes needs to be written out. This is done by flushing each of the mounted volumes. This operation normally happens very quickly. However, updating volumes over a network can sometimes take time if the network is busy. This is not something that AppleTalk or AppleShare takes care of, but a job that the Finder does.

MacTCP: BOOTP/RARP Server Priority

Can I change the order that MacTCP looks for server addresses? My problem is that MacTCP uses RARP first (which then times out after 8 seconds) before then using the BOOTP protocol. Is there a way I can rearrange the order so that BOOTP comes up first before having an 8-second delay?

This article has been archived and is no longer updated by Apple.
According to MacTCP Engineering, MacTCP remembers what protocol was successful in acquiring its IP address over startups, so that the successful protocol is tried first. In other words, once MacTCP has located and acquired an IP address from a BOOTP server it then uses the BOOTP server before trying the RARP server the next time MacTCP is used. The first time MacTCP is used, the RARP server may be tried first. However, this should not continue once the BOOTP server is located.

There is currently no way to configure MacTCP to select server priority via a control-panel device or by using ResEdit.

A/UX: UFS Subdirectory Limit (9/94)

I came across an interesting limitation problem of A/UX 2.0: You can create only 1000 subdirectories within a directory. After that, mkdir won't make any more subdirectories. Instead, you get the message:

mkdir: another: Too many links

We need to create more than 1000 subdirectories inside one directory because the software we are porting to A/UX creates a directory for each department at the University, and there are more than 1000 departments.

This article has been archived and is no longer updated by Apple.
We have verified that there is a limitation on the number of subdirectories created within a directory under A/UX 2.0 UFS file system. The maximum is 1000. This is defined in the /usr/include/sys/param.h file with a line:

#define MAXLINK 1000 /* max links */

The maximum number of subdirectories under A/UX 3.0 is 32,767.

A/UX: uucp and Mail Questions (9/94)

I am trying to write a script for an L.sys file that will let me connect to a 3B2/1000 machine via ISN using uucp. The beginning of the script looks like this:

"" ATD555-1212, expect nothing send dial string
2400 \\r\\r expect 2400 send two carriage returns

This is where the confusion starts. The carriage returns must be sent to set the line characteristics (autobaud). When I manually use cu to connect, the two carriage returns typed are not echoed, but a 4- or 5-line banner is sent back.

When I call with the line

uucico -r1 -sLAB -x9

the chat dialog cranks up and the number is dialed. However, when the modem answers, the 2400 is picked up by the script. The modem then flashes the TX light. I assume this means the carriage returns are being sent. However, the RX light never flashes and uucico hangs and eventually times out.

I don't believe the Welcome header is being sent. I have tried

\\r,,\\r

and several variations, i.e., more carriage returns and a variety of commas in various positions. I have a feeling that only one carriage return is being sent. This carriage return does not echo, and the program waits forever, because the header will not be sent.

1) Does uucico send characters one at a time and wait for the echo before sending the next one? This would account for the hang, because the first two carriage returns are munched by the autobaud mechanism.

2) If the answer to the above is yes, is there any workaround? I tried \\e\\r\\r but got the same results.

3) Assuming I can finally get the carriage returns processed and cause the header to be sent, do I have to process each line of the header with an "expect-send" pair, or can I simply "expect" the tail of the last line of the header?

I solved the problem of the autobaud not echoing characters. Recall that I have to send several carriage returns to get the attention of the system after I get the connect message from the modem. Instead of sending \\r\\r\\r (only one of the carriage returns evidently get sent), I now send

\\r\\c "" \\r\\c "" \\r\\c

It looks like the above line sends one carriage return and expects nothing, sends another carriage return and expects nothing, and sends one more carriage return.

This seems to do the trick. The header comes flying by and I can then negotiate into the nuucp login. Because I can send files to the machine without any problem, uucp seems to work okay. However, mail does not seem to work. I have tried:

mail name!user and
mailx name!user and
rmail name!user

After I exit the mail programs, nothing happens. There are no log files created in the spool area, and the phone never goes off hook. It seems like the letter drops into a black hole! If uucp works, why doesn't mail work? (I am using ksh.)

This article has been archived and is no longer updated by Apple.
Usually, people play trial-and-error on the "expect" and "send" strings in the L.sys to find communication line (modem or other device) characteristics, like "Connect", "Online", and other message outputs from the modem. uucico sends the "expect-send" pair of strings to the remote uucp host via the communication line. It depends on how the underlying communication device behaves itself. For example, does it require a carriage return or a new line or a couple of delays while in conversation mode? Below are special characters often used in the "expect-send" string:

\\r CARRIAGE RETURN
\\d DELAY for one second
\\c NO NL (No New Line)

A delay (\\d) is sometimes needed for uucico to wait for the communication line to complete its task before process the next string.

The "expected" and "send" string pairs are processed in that order. Yes, you may grab the last line of the display message as the "expected" string. For autobaud to work, you can try the '"' \\r\\c '"' \\r\\c "expect-send" sequences.

If uucp works, it does not necessarily mean that the "mail" should work. It depends on how the "sendmail" system is set up and configured. Is the "sendmail" program up and running on both machines?

The /usr/spool/mqueue/syslog file should record the reason for the mail problem. However, the /etc/syslogd daemon must be running to show the sendmail activity.

MacX: Adding X Fonts (5/95)

How and in what form are additional fonts added to MacX under A/UX and the Mac OS?

This article has been archived and is no longer updated by Apple.
The procedure is identical for adding X fonts for both A/UX and Mac OS to the MacX Font Director list. The Font Director is built in MacX, which can be invoked by selecting "Fonts..." from the Edit menu. The Font Director lets you view, add, and remove existing Macintosh fonts to and from the font directory list. It also compiles fonts from the BDF (Bitmap Distribution Format) files.

To add "X fonts" into the MacX Font Directory list, the X font must be converted into a BDF file, so that it can be compiled by the Font Director and added into the font directory list.

The public domain software called "snftobdf" converts a SNF font file into a BDF font file.

A/UX 2.0: Screen Dimmer Enhancement Request (6/92)

I am looking for A/UX-compatible screen-dimming software. I want it to be active once logged in and while at the login screen. For that to take place, will the application have to reside in multiple System folders?

This article has been archived and is no longer updated by Apple.

We know of some screen dimmers, like "Blackout v1.21" and "Pyro 4.0", that work under A/UX 2.0. "AfterDark" seems to have a problem with "unsupported status csCode ..." if the SCRN resource is not removed.

"Blackout v1.21" seems to work under both "before" Login screen and "after" Login screen. For "Blackout v1.21" to work on both "before" and "after" Login dialog screens, the "Blackout v1.21" puts both folders (/mac/sys/'Login System Folder' and the /mac/sys/'System Folder') in the System folder.

A/UX 2.0: 3270 Terminal Emulation

1) I am working on a Macintosh IIx with A/UX 2.0 and a Kinetics EtherPort II. The company where I work has lots of Sun systems, DOS machines, and IBM mainframes (even a few Crays). TCP/IP is the prevalent Comm protocol.

Using Telnet, we have no problem logging into IBM mainframes running TCP/IP. A/UX does not seem to have a 3270 terminal entry, so the 3270 screens don't appear as they should. Is there a 3270 type of term entry that will let the screens appear correctly under CommandShell?

2) I tried to use Intercon's TCP Connect II. This package does provide 3270 terminal types via Telnet. Running from A/UX, the program lets you log into a local Sun, but I can't seem to get across the router. The Intercon tech support engineer didn't have an answer other than running under Macintosh OS and setting the gateway address in the "Admin TCP" CDEV. Looking at the "MacTCP" CDEV under A/UX, the gateway field is 0.0.0.0 even though the route command has been run. Do you know why I can't get past the router from TCP Connect while running under A/UX?

This article has been archived and is no longer updated by Apple.

1) There is currently no 3270 termcap entry for a 3270 session in A/UX 2.0 /etc/termcap file.

However, there is a software package called tn3270, which, we believe, came with the 4.3BSD distribution. It provides a solution for talking to IBM hosts running VM/CMS with the University of Wisconsin who developed TCP/IP codes. The tn3270 also includes a file called "map3270", which contains mapping between characters entered from the keyboard and 3270 keys used by the "tn3270" program doing 3270 emulation from UNIX. Tn3270 requires the 4.3BSD curses to run.

Porting 4.3BSD tn3270 to A/UX or using the third-party tn3270 product would be the ideal solution.

"Admin TCP" is not needed by A/UX 2.0 MacTCP since TCP/IP is configured by A/UX "ifconfig" and other network services, like Domain nameserver and/or gateway. You only need "MacTCP" in the System Folder.

2) We have no experience with the TCP/Connect II software. Is there any control file provided by TCP/Connect II to specify the gateway and/or the domain name server to be used? Like in NCSA Telnet 2.3, the "config.tel" file may contain information on gateways and name servers. We have tested the NCSA Telnet 2.3 with MacTCP in A/UX 2.0 to a remote host via a gateway (router) without any problem. The gateway information is generated by the A/UX "/usr/etc/route" or the /etc/in.routed" process as all information in
A/UX MacTCP is disabled and can't be changed.

AppleTalk: Configuring under A/UX (8/94)

To configure AppleTalk under A/UX, must bnet be configured? If yes, is it a bug or are the protocols stacks linked?

This article has been archived and is no longer updated by Apple.
Yes, to run AppleTalk you should have the "bnet" configured in the A/UX kernel. That means before doing "newconfig appletalk", the A/UX kernel must have been configured with "bnet". The reason is that AppleTalk modules link some modules from "bnet". The linked bnet modules include "m_get", "m_freem", and so on. In short, AppleTalk uses B-Net socket system calls to do inter-process communication for AppleTalk printing service. Note that the default A/UX 3.0 distribution is configured with "bnet" and "appletalk" driver modules.

It is not a bug; as you stated, the protocol stacks are linked.

AppleShare Workstation Server Limit

I have a program that automatically backs up our server volumes from a workstation. The problem is that I need all the volumes to be mounted on the workstation for the automatic back up to work. I want to run the software on a 2.5MB Macintosh Plus with an 80MB hard drive running System 6.0.3. I am trying to mount 8 volumes. When I try to mount the fourth volume, I get a message about not being able to open any more volumes.

What is the limitation? RAM? System software? Would a different computer help: Macintosh SE, Macintosh II? How many volumes should a workstation be able to mount?

This article has been archived and is no longer updated by Apple.
There is a limitation in the number of servers that a given Macintosh computer can be logged on to at one time. The number of servers by machine is as follows:

Computer	Number of Servers
Macintosh Plus	3
Macintosh SE	8
Macintosh Classic	8
Macintosh Portable	8
Macintosh LC	18
Macintosh SE/30	18
Macintosh II	18
Macintosh IIx	18
Macintosh IIcx	18
Macintosh IIsi	18
Macintosh IIci	18
Macintosh IIfx	18
Macintosh PowerBook 100	18
Macintosh PowerBook 140	18
Macintosh PowerBook 170	18
Macintosh Quadra 700	18
Macintosh Quadra 900	18
Macintosh Classic II	18

There is also a limit in the number of volumes you can have mounted. When a volume is mounted, information about that volume is loaded into System and Finder memory. The amount of memory needed to mount a volume is dependent on the size of and the number of files on that volume.

Monitors: Earth‘s Magnetic Field Affects Performance

Variations in the earth's magnetic field can affect a monitor's performance, especially if it is moved from one hemisphere to the other.
This article has been archived and is no longer updated by Apple.
Monitors based on cathode-ray tube (CRT) technology, including those found in iMac computers, use precisely controlled magnetic fields to direct the flow of electrons to the red, green, and blue light emitting phosphors on the monitor. The earth's magnetic field varies in intensity throughout the world, which can affect the path of this electron beam. During manufacturing, CRT-based monitors are aligned in special areas called helmholtz cages that simulate the magnetic field the monitor is being aligned for. Monitors are typically aligned for the Northern Hemisphere or the Southern Hemisphere, and sometimes for the equatorial region.

A CRT-based monitor purchased in the Northern Hemisphere may not perform correctly if it is moved to the Southern Hemisphere. The reverse is also true because the earth's magnetic fields are not the same in each hemisphere. A monitor moved to another hemisphere may encounter color purity problems that cannot be adjusted out. It is technically possible to realign a monitor to work in a different hemisphere, but the skills and specialized equipment required make it prohibitively expensive for most purposes.

Liquid crystal displays, such as the Apple Cinema Display and the display of an iBook computer, are not affected by the earth's magnetic fields, and can be moved between the Northern and Southern Hemispheres.

A/UX and Raw Sockets (8/94)

I want to use raw sockets in A/UX so that I can set up a TCP/IP address server. I want to use the raw sockets to check dynamically on the availability of a TCP/IP address and load an available address into a particular platform.

This article has been archived and is no longer updated by Apple.
This sounds like a developer programming issue. The "A/UX Network Application Programming" documentation is a good reference for writing sockets which include Stream, Datagram, and Raw sockets. It also includes some sample C code. Section 11 of 4.3BSD "Networking Implementation Notes" describes details on what raw sockets are, what their control block structure is, and how the input and output raw sockets are processed. These notes regarding how raw socket addresses are handled might be of interest:

A raw socket interface is datagram oriented. That is, each send or
receive on the socket requires a destination address. This address may
be supplied by the user or stored in the control block and automatically
installed in the outgoing packet by the output routine. Since it is not
possible to determine whether an address is present or not in the
control block, two flags, RAW_LADDR and RAW_FADDR, indicate if a local
and foreign address are present. Routing is expected to be performed by
the underlying protocol if necessary.

You should also examine the rules of raw socket input and output processing and see if the rules fit their TCP/IP applications.

The "A/UX Network Applications Programming" document and "A/UX Development Sources" Version 2.0 on CD-ROM are available from APDA. If you need immediate assistance on developing their socket codes, we suggest that, as a developer, you contact MacDTS (Macintosh Developer Technical Support).

MacDFT: Apple 12-Inch RGB Monitor Issue

Is MacDFT 1.1.1 compatible with the new Apple 12-inch color monitor?

If I open a dialog like Display or Keyboard, I don't get the whole box in the picture. If I then open and close it repeatedly, the whole text moves upwards, so after a few tries I don't see any text at all.

If I check Resize Fonts, nothing changes. How is that supposed to work? I thought that if I checked that, MacDFT would change the font size, if you changed the window size.
This article has been archived and is no longer updated by Apple.
We found there are some display problems when using MacDFT with an Apple 12-inch RGB monitor, for example the menu items Display and Keyboard aren't fully displayed on the screen. However, we didn't find limitations so severe as to prevent you from using this combination. We reported this problem to Engineering.

When you check the Resize Fonts option, the text on the screen will not change point size as you shrink or enlarge the window. Instead your options are:

Resize font: unselected
If you use this default setting, the window changes to accommodate the rows and columns. The font size remains the same size chosen from the Font size menu. This choice lets you display the full column width associated with each model type, except for Model 5, where you must use the horizontal scroll bar to see all 132 columns.

Resize font: selected
If you select this option, MacDFT changes the font size to fit the terminal model you have selected. If you choose this option, you can see all your columns and rows. In some cases, the window may not be able to display all the rows and columns, and you must use the scroll bars to display some data. The window size also changes to accommodate the extra rows and columns.

Both of these options are described and illustrated in the "MacDFT User's Guide."

Apple IIGS: How To Pick Up Video Blanking Signals

This article has been archived and is no longer updated by Apple.

There is no way to physically pick up the video blanking signal since it is now buried inside the VGC chip. However, through software, there are two ways to pick up this signal.

1. Arm the Vertical Interrupts as one would do with an Apple IIc.
2. Read the Vertical Blanking location at $C019 as one would do with an Apple IIe.

Research the appropriate manual for how to do these operations. If a routine is written to handle video timing for the Apple IIe by picking up video blanking signals from an IO chip (UE5), the routine can be converted for the IIGS environment with these two techniques.

My original problem was that I could get one copy to print out, but when I tried printing again, all I would get was blank paper.

I think the problem may be is with the EOF character. Does the LaserWriter require and EOF character? If so, does the ImageWriter Emulator supply the EOF character, or is that the responsibility of the software package?

This article has been archived and is no longer updated by Apple.
The LaserWriter requires an EOF character (in this case Form Feed, ASCII 12). The ImageWriter Emulator does not supply this character; it must be supplied by the application doing the printing. Stone Edge should be able to help you configure the software to do this.

MacPAD: Changing Default Parameters

I need to change the MacPAD parameter 3: "Data Forwarding Character" to "after each character" but the software doesn't offer a menu for this. I'm assuming the defaults are stored somewhere in the resources of MacPAD. I need to know where and how these PAD parameters are stored in the resources, so I can change the default parameters.
This article has been archived and is no longer updated by Apple.
Because of the way the parameters like "Send data on every alpha-numeric character" are stored in MacPAD, they cannot be modified easily with ResEdit. Furthermore, as soon as a connection is established, the other side might use X.29 to modify the parameter anyway.

Macintosh Communications ToolBox applications, like MacTerminal 3.0, can save Settings or MacPAD parameters when you choose "Save Changes". Looking at the "Comm Toolbox Reference" manual, config and oldConfig point to the MacPAD private data block, which is called automatically when you create a connection record (CMNew automatically makes two calls to CMDefault to fill in confg and oldConfig). Your program needs to store the contents of config to save the state of the connection tool.

The above assumes you are using MacPAD at all. Perhaps the program writes directly to the X.25 Interface Library? If so, your program then must assume more responsibility in setting up and tearing down the call. Lastly, the CCITT X.28 allows for only certain PAD profiles and to impose other profiles that may violate the specification.

MacX: Repainting Rooted and Rootless Windows

Does our Apple X11 server (MacX) store the window image locally, so the window can be repainted locally if it is clipped, or does the host have to send down the image to repaint the screen?

This article has been archived and is no longer updated by Apple.
There are three possible scenarios involved in this question, depending on the window types you have specified.

If you have rootless windows (in other words, each X-client application is running in a separate Macintosh window), then each window's image is stored locally in an offscreen bitmap. This prevents the necessity of having the client application redraw the information.

The next two scenarios involve rooted windows, which are two different issues.

The first issue is what happens to the entire rooted window when it is forced to update itself. In this case, the currently-displayed rooted window's image is stored in an offscreen bitmap, and the updates are done locally and not by the client applications. This is consistent with the method used by the rootless windows as mentioned above and is necessary, because X client applications are typically not prepared to deal with changes to the root window itself.

The second issue is involved with multiple X-client windows within the single Macintosh root window. In the situation where you have overlapping X windows within the rooted window, and you are switching between the windows, the client applications are responsible for updating the clipped regions just as they should be.

Perhaps the best way to think of this is that the images contained within Macintosh-style windows are stored locally.

VTAB statements move the cursor to a specific vertical position ignoring the current text window.

This article has been archived and is no longer updated by Apple.

A VTAB to a line above the text window starts writing as if the window were the whole screen until it scrolls into the window where it stays. This prevents the information above the window from scrolling. A VTAB below the window causes writing only on the line where the cursor is located, allowing normal scrolling within the window from carriage returns.

LaserWriter: PostScript Command For DTR Protocol

This article has been archived and is no longer updated by Apple.

To interface a LaserWriter with an IBM compatible, WordPerfect 4.2, which now claims support for the LaserWriter, furnishes a segment of PostSript code with the file name INITWRT.PS. This file, according to their instructions, is to be sent to the printer via the serial port to change the EEROM so that the LaserWriter will thereafter support a hardware protocol, specifically DTR.

Leaving out the comments and password checking, the essential PostScript code that is sent to the LaserWriter is

25 9600 7 SETSCCBATCH

The channel and baud numbers are default, but the LaserWriter Technical manual mentions only integers 0 through 3 for the parity position and mentions nothing about 7.

The code would have no effect on the AppleTalk Network. This code makes changes strictly in the LaserWriter and then only where specified by the code (batch or interactive). This code does not affect the "SPECIAL" mode. SCCBATCH is only for the "9600" or "1200" switch positions in Diablo emulation mode for using PostScript with the printer. The "SPECIAL" mode is controlled by SCCINTERACTIVE, and the line

25 9600 7 SETSCCINTERACTIVE.

could control the Diablo 630 mode functions under 9600 and DTR protocol.

The only problem is that unless the user has a LaserWriter Plus or a LaserWriter with 2.0 (or later) ROMs in it, this "7" command is useless. Since the LaserWriter only supports Xon/Xoff flow control, any command sent to set up DTR handshaking will not function, and there may actually be some strange actions from the printer if it is attempted. If they don't have 2.0 or later ROMs in their LaserWriter, do not use this code.

Macintosh Classic: Boot ROM Option Is Not a Supported Feature

I'm testing some features of the Macintosh Classic; in particular, the Boot ROM option (Command-Option-X-O). It's really fantastic, but we (outside the U.S.) have a problem with the International Resources such as keyboard resources. When booting from ROM, you are automatically in QWERTY mode. It's "normal," but what can be done for people who are using AZERTY or something other than a QWERTY keyboard?

This article has been archived and is no longer updated by Apple.
The Boot ROM option isn't a supported feature in either domestic or international versions of the Macintosh Classic. The code was part of an experiment in future directions and wasn't taken out before the ROMs were finalized.

Because the software in use was not fully tested with the Macintosh Classic, we don't recommend its use in any way.

Macintosh RS-422-to-RS-232-C Adapter

I am trying to attach some Macintosh computers to a AT&T ISN network. The ISN requires an RJ-45 connector. We are having two problems.

1) According to the article "Macintosh Mini-8-to-RJ-45 Connection", "To do this, you need some kind of adapter." Is there a way to build a RS-422-RJ-45 cable without an RS-232 adapter in the middle?

2) Is there a consistent difference between computers in the Macintosh II family and Macintosh SE computers in terms of distance tolerance for RS-422? We get a Macintosh SE to work in situations where a Macintosh IIci will not. My thought was similar to that in another article on serial port cable length specifications. That is, we were a little over the distance spec and the Macintosh SE seems to be able to handle that. Word on the Internet is that people have to make different cables for the Macintosh II than for the Macintosh SE in these situations.

This article has been archived and is no longer updated by Apple.

Because the built-in Macintosh serial ports are based on RS-422, which uses differential signals, a simple rule should be followed to assure compatibility with RS-232-C devices. Ground the RD+ line and leave the TD+ line disconnected. This converts the port to RS-423, which is compatible with almost all RS-232-C equipment.

The adapter spoken of in the article you referenced merely adapts the different connector types: RJ-45 to DB-25. The grounding of RD+ was done by the Mini-8 to DB-25 adapter. The following diagram shows the proper cable configuration for connecting a Macintosh serial port to an RS-232 device:

```
 Macintosh Mini-8 Port                          25 Pin RS-232 DTE Device
 Signal Name    Signal  Pin                     Pin* Signal  Signal Name
 -------------  ------  ---                     ---  ------  -------------
 Handshake Out  HSKo    1  ---- if needed --->   6   DSR     Data Set Ready
 Handshake In   HSKi    2  <--- if needed ----  20   DTR     Data Term Ready
 Transmit -     TD-     3  ------------------>   3   RD      Receive
 Receive -      RD-     5  <------------------   2   TD      Transmit
 Transmit +     TD+     6  Not connected
 Signal Ground  SG      4  -----|-------------   7   SG      Signal Ground
 Receive +      RD+     8  -----|
```

*Note that the pin assignments shown may be wrong if the RS-232 device is wired as DCE instead of DTE. Since we don't know how the RJ-45 connectors are wired, we can't provide pin assignments for them. However, the signal assignments will be the same, so you can translate pin numbers from the signal names.

Although both Macintosh ports usually work with RS-232-C equipment without the considerations mentioned above, their maximum cable lengths and resistance to noise and interference are reduced. The approximate 50-foot length limitation may be reduced drastically and reliability can be impaired.

We have noticed that the Macintosh SE and earlier models are slightly more tolerant of cable design. While the Macintosh II family serial ports are capable of the 50-foot maximum cable length RS-232-C specification, this requires the cable to be designed as shown above. If RD+ is not grounded, the maximum length will be reduced. The Internet community discussions you

mention are probably based on a partial understanding of these factors.

A/UX: MacX and Native X Performance (9/94)

I need to optimize an A/UX system for running X Window System applications in the following environments:

1) Running Native X Window System under A/UX on a Macintosh IIfx,
running with 16MB or 32MB of physical RAM.

2) Running MacX in the Finder under A/UX on Macintosh IIfx,
running with 16MB or 32MB of physical RAM.

The applications are X based, using pull-down menus extensively. Of the two, running under MacX is going to be weighed most heavily. I will be using the MacX 1.2 that comes with A/UX.

Does running the same application in a rooted color window versus rootless color window affect performance one way or the other?

I've used the following method to optimize A/UX for Native X Window System under 8MB of memory:

For systems with 8MB, bring A/UX up as single-user, then run these commands:

```
# kconfig -n /unix
NBUF=2500
NINODE=600
NFILE=400
<Control-D>
# sync
# sync
# sync
# reboot
```

When doing this though, MacX performance under A/UX on the same machine crawls slower than before.

This article has been archived and is no longer updated by Apple.
Performance should not be affected when selecting a rootless color window or a rooted color window when running the same X client application.

The above kernel parameters, especially NBUF=2500, seems to be too high for an A/UX 8MB system. The "NBUF=2500" itself takes up 5MB (2500 x 2K) of existing memory. When you add the other kernel parameters, there is not much available physical memory left for applications. This will cause more paging activity and, in turn, degrade the performance.

If you have 16MB or 32MB of physical memory on a Macintosh IIfx running A/UX 3.0, the same kernel parameters configuration should be feasible to run either X11 Window System or MacX under A/UX.

The system performance will really depend on how many X client applications and other applications, including Macintosh applications and UNIX processes, are running at the same time in A/UX and the underlying network environment in which A/UX resides. The following kernel parameters should be adjusted accordingly to fit your running environment:

NBUF If NBUF=0, it allocates about 10% of free memory for disk block I/O buffers.

NFILE is the size for system file-table pool (600 seems fair enough).
NINODE is the size for system inode-table pool (400 seems fair enough).

NPROC is the maximum number of processes allowed in the system.
MAXUP is the maximum number of processes per user allowed in the system.
NMBUFS is the maximum number of buffers allocated for networking.

Each NMBUFS buffer requires 256 bytes. The more network daemons running, the more mbufs are needed for memory allocation.
Since both MacX and X11 must be run at least in an A/UX B-Net kernel, the NMBUFS must be set fair enough for the network buffering. By default, 500 mbufs are allocated. For an A/UX with NFS and/or YP A/UX kernel, the NMBUFS needs to be increased significantly, say 1000 or 1500.

The "netstat -m" can be used to display the number of mbufs currently in use.

Also, the "pstat -m" command can be used to display information about the current memory allocations, which include the number of I/O buffers (NBUF) allocated, the number of inodes (NINDOE), and the file (NFILE) currently active.

A/UX 2.0: "fcnvt" May Create Bad MacBinary Header (8/94)

The 'fcnvt' tool supplied with A/UX 2.0 sometimes creates a MacBinary file with a bad header. Attempts to download this file to a program that receives MacBinaries (like Microphone) fails, in that it does not recognize the file as a MacBinary file. This seems to occur usually when converting a BinHex file (like one downloaded off of USENET) to MacBinary with the following command:

fcnvt -i hex -m filename

This article has been archived and is no longer updated by Apple.

Look at the MacBinary file that is created, and you'll notice that byte $4A is non-zero, which is incorrect, according to the MacBinary Standard. Also, byte $49, which should contain some of the Finder flags, usually seems to contain incorrect information. Setting byte $4A to zero seems to fix the problem--the file will then successfully download. Note that when creating a MacBinary from an AppleSingle file, these two bytes seem to be okay and the file downloads okay.

Macintosh II: Video Overview (3 of 3) (2/95)

This is the last part of a three-part article describing how the Macintosh II produces video.

This article has been archived and is no longer updated by Apple.

Color Burst

A reference signal by which color signal values can be determined. The phase of a color signal in relation to the color burst signal indicates hue. This is located on the trailing edge of the horizontal video signal and is known as a back porch.

Chrominance

The 3.58MHz subcarrier that contains the signal for color value of each pixel:

Red signal: 90 degrees out of phase
Green signal: 0 degrees out of phase
Blue signal: 180 degrees out of phase

The red, green, and blue signals (RGB) can vary in hue depending on their phase with the sync signal. A variation in signal magnitude increases or decreases the intensity of the color.

Macintosh II Video Modes Revisited
---
* RGB RS343 compatible is an RGB video signal with separate TTL sync. It is timed by a 30.24 MHz oscillator. 1 volt signal. 75 ohm terminated. An analog standard level sync is available on green.

* RGB RS170 interlaced is an RGB video signal with sync. It is timed by a 12.2727 MHz oscillator. Its horizontal signals are alternately spaced in relation to the vertical blanking period. The electron beam moves down from the left corner to the right and from the bottom right corner to the top, to begin again in the center or the corner of the screen. In this way, there are twice the of number rows than are being displayed in each frame. Each row follows a slightly slanted path. One begins at the top left corner and slants downward, while the other begins from the top and center. These interlaced lines provide a greater number of images to the eye, to compensate for a slow refresh time.

In the RS170 mode, the sync signal has been combined with the green signal. A television or similar monitor could take advantage of this signal in black and white only.

Picture Quality

Bandwidth is the signal width. It describes how much information is being delivered. The higher the bandwidth, the more video information that can be delivered and displayed by a monitor.

Pixel size is the size of the phosphor dots on the screen. It determines the precision in which the video information can be duplicated.

Dot pitch is pixel size.

Scan rate is the time period in which the electron gun moves across one line of the screen or repeats one entire screen. These values are known as the horizontal and vertical sync periods, respectively.

Grill pitch is the width of the lines in the color mask used to block the color electron beams. It is usually measured at the phosphor positions, and is synonymous with dot pitch.

Pin cushion is a display effect of warping or curved display screens.

Convergence is beam position accuracy. Color systems require exact accuracy of beams, both for position and speed, to properly produce the desired colors from their phosphors.

Applesoft BASIC: Moving a Listing to a Macintosh and Back

I would like to use a Macintosh word processor to edit Applesoft BASIC files from the Apple II environment. Is there a translator to take "tokenized" Applesoft BASIC files and have them appear on the Macintosh? The tokens (PRINT, DISPLAY...) don't seem to get translated when files are moved to the Macintosh. The original version of Passport (Apple File Exchange) had that capability.

This article has been archived and is no longer updated by Apple.

We don't know of an AFE Translator for Applesoft BASIC files to Macintosh text files. You can get around this limitation by "printing" the Applesoft program files to a disk file before the AFE conversion. After editing on the Macintosh, transfer the files back to the Apple II. Then, EXEC each file to make it an Applesoft file. To do this, add the following code to the existing Applesoft program:

```
1 D$ = CHR$(4)
2 PRINT D$; "OPEN PGM.LIST"
3 PRINT D$; "LIST"
4 GOTO 32766

add the existing Applesoft program here

32766 PRINT D$; "CLOSE PGM.LIST"
```

The entire Applesoft program will be saved in a text filed called "PGM.LIST" and can be converted to a Macintosh format for editing.

After editing is complete, transfer the file back to Apple II text format using the file name "EDITED.FILE". Use the EXEC command to turn the text listing into an Applesoft program in memory.

```
] EXEC EDITED.FILE
```

Be sure to SAVE the program to disk or the EXEC step will have to be repeated each time the user wants to run the program.

MacTCP: Using DDP/IP Gateway to Get Dynamic IP Address

In MacTCP, you can choose to set the addresses dynamically. If you do this, when does the server let go of that address? My problem is that every node that logs on never lets go of an address -- so in a short time, all addresses are taken although only a few people are logged on.
This article has been archived and is no longer updated by Apple.
With MacTCP set to do dynamic addressing, the user fills in the Network portion of the IP address. A Macintosh computer configured in this way dynamically assigns itself an IP node address based on this network address, and tests to see if this address is in use. If the address is not being used, MacTCP uses it, and does not release it until the computer is shut down.

MacTCP also supports server-based addressing through either Ethernet (bootp), or AppleTalk (DDP/IP). An unsuspecting user might configure both dynamic addressing, and bootp or DDP/IP addressing with the result that the Macintosh computers will assign themselves node IDs in the network range entered in MacTCP, but never consult the bootp or DDP/IP server.

The correct setting in MacTCP for server-based addressing is server, not dynamic. Server addressing through AppleTalk is either EtherTalk, LocalTalk, or Apple Remote Access; while dynamic addressing means independent arbitration.

AppleTalk: Worldwide Network Issues

I have three questions involving AppleTalk on a worldwide network at a top investment bank:

1) Are file accesses across the net controlled by AppleShare, or is something else controlling the file access?

2) When the packet-switched network re-routes lines, we can experience delays of 5 minutes or more. The connections re-route, but usually we seem to lose our network file connection. What happens to an AppleShare request when its response is delayed for that long? We saw (using a datascope on the line) that if the request for servers timed out, the response was ignored. Does a similar situation take place in the case of a read?

3) Does the modification to the GNRL resource affect only the initial call? If the server becomes available quickly, does that shorten the time-out that AppleShare will use for all server access while the server is mounted?

This article has been archived and is no longer updated by Apple.
1) AppleShare (AFP calls) controls all access to the remote files, including the handling any time-out values associated with the function of accessing a file. By " controlled", we assume you mean any function that pertains to successfully opening, reading, or writing to a file stored on an AFP server. There are many AppleTalk protocol functions associated with AFP transactions that are not directly considered a controlling aspect of manipulating a remote file. These functions do not control access to the individual files so much as they control access to the media being using to transport the AFP calls.

If you are using standard file system calls and if the file you're trying to access is located on an AFP server, all local file system calls such as PBOpen, PBRead, FSRead, etc. are filtered out and transformed into equivalent AFP calls.

2) The 5-minute delay is going to present a real problem to AppleShare, or to be more precise to the ASP protocol. The session timer for an AppleShare file server connection is set to 2 minutes. Once this timer expires, the session will terminate, and you will lose your server connection. The retry count for the read request is set to infinite, so a read request never really times out.

The session timer is restarted each time a tickle packet is received by either the workstation or the server. Tickle packets are sent out every 60 seconds by both the server and the workstation as part of the ASP protocol, to allow a way of detecting that the other end of the connection has gone down. There is no easy way to reset this timer value.

3) If you modify the GNRL resource in the AppleShare chooser document, it will affect every NBP lookup that is done from the Chooser. The Chooser uses these values to determine the NBP lookup interval and retry values for the current NBP transaction. The default of 0705 tells the chooser to send 5 NBP lookup requests at an interval of 7/8 second. This process is repeated in an infinite loop until the user closes the Chooser.

Chooser Event Flow Example:

User opens chooser and selects the AppleShare CDEV
GNRL resource -4096 loaded = (5002)
NBP look up mechanism started

NBP Loop:
Get NBP ID for this transaction
(Note: All NBP request and replies for this loop will use
this ID)

Send first look up (NBP ID = "New")
Collect and display responses from the NBP look up ID "New"
Wait 10.6 seconds

Send second look up (NBP ID still = "New")
Collect and display responses from the NBP look up ID "New"
Wait 10.6 seconds

Discard all buffers and data associated with NBP ID "New"
(Note: If a response is received for NBP lookup ID = "New"
after this point the reply data would be discarded and the
device would not be added to the list in the Chooser.)
Do some other misc. cleanup (approximate time, 1 second)

goto NBP Loop
End NBP Loop:

With the retry timer set to such a large value, the multiple retry count is really not necessary. On the other hand, it doesn't hurt anything either, and it effectively increases the time you'll wait for NBP replies to over 20 seconds for the current transaction. The idea behind the retry count is to send several lookup requests in quick succession (default is less than 1 second) in case there are devices which cannot respond, because they are busy or because the previous packet never reached them.

The reason that increasing the interval timer helps in the case of remote servers is directly tied to the way the NBP mechanism works. The chooser maintains only 1 NBP lookup request at a time, tracking all replies to that request by way of the NBP ID mechanism. Replies that are received that do not match the current request ID are discarded. The request ID is maintained only for the current NBP request; the interval and retry counters for this request can be tuned via the GNRL resource. In other words, if you set the retry counter to 10 and the interval timer to 50, the NBP ID would be maintained for 10 requests at an interval of 10.6 seconds. The GNRL resource is documented in "Inside Macintosh, Volume 4," page 216.

Font Substitution Disabled with "Fractional Widths" On

My PostScript printer won't print using Font Substitution when printing from a Macintosh Plus. "Fractional Widths" are set to on, thus preventing Font Substitution from occurring. I need a way to turn off Fractional Widths without using some program like Microsoft Word. Our office uses MacWrite versions 4.5 and 5.0. We want to compose documents in Geneva and print with a PostScript font (Helvetica). Is there some INIT or small program that turns off Fractional Widths to allow Font Substitution? Alternatively, is there a good, readable, public-domain, bit-mapped Font that will substitute for the bit-mapped Helvetica? With it, can I create documents in this font and print them in Helvetica with Fractional Widths on?
This article has been archived and is no longer updated by Apple.
You raise a couple of issues we'll attempt to address below.

You mention a problem that your print job won't "print" when you use Font Substitution. During our experimentation, we encountered an intermittent bug with MacWrite. Text imported to it via the Clipboard (copy and paste) didn't always print, regardless of whether font substitution is on or off.

The print job would appear to download to the printer OK, but the job would flush without printing (blank paper comes out of the printer). This is a problem Claris is aware of, and they recommend saving the document to a text format from whatever application you are using, then opening the file from within MacWrite.

You state that when Fractional Widths is enabled, font substitution will not occur. This is a correct response. Font substitution is disabled in all cases where fractional pixel widths are enabled. The default for Fractional Widths is disabled. It is the domain of the application to enable it if desired.

We don't recall ever seeing a utility that will toggle SetFractEnable on and off, but such a program doesn't make a lot of sense to us, as each program needs to call SetFractEnable in the Macintosh ROM. One application's setting will have no effect on another program's setting.

We don't think substituting a bitmapped LaserWriter font will help here. Aside from the printing problem you report, one possible workaround is to select Helvetica as a screen font, so no font substitution will be required at all when printing. To this end, Claris made Helvetica the default font in MacWrite II. MacWrite has no provision for turning off fractional widths. However, MacWrite II does have this ability. Upgrading to MacWrite II may be another option.

Another alternative is to change the document's font to Helvetica prior to printing, perhaps using a program like QuicKeys to streamline the operation if desired.

AppleShare: Product to Limit Concurrent Launches

I have a question about shared applications on an AppleShare server. I want the ability to restrict the number of concurrent launches of an application to the number licensed from the application's vendor. We know that AppleShare doesn't do this now, and the Macintosh OS doesn't necessarily support this function either.

OS/2 LAN Manager has this capability, and people are using this function to save money and reduce support costs by having only one copy of the application to update for all of its DOS users on the network.

Do you know of any third-party utilities that will restrict the number of concurrent launches to an application on a server? Granted, application vendors don't normally license their software this way. However, I could still purchase x number of copies of an application and then impose the limit of x concurrent launches of the application and still save money on the support costs and the reduce the total number of copies that would be needed.

This article has been archived and is no longer updated by Apple.
You are correct that AppleShare doesn't now limit the concurrent number of times an application is launched.

AppleShare Product Management brought to our attention a product described in the following article (by Eric J. Adams) from the March 13, 1990, issue of MacWEEK:

"Hanover, N.H.--A Dartmouth College math professor has developed a network-based software-management program that solves several problems associated with distribution and piracy prevention.

"The program, called KeyServer, is now in use at Dartmouth, and its developer, Dr. Denis Devlin, hopes to begin commercial marketing later this year.

"KeyServer's installation program lets administrators modify popular applications, based on the provisions of their site license, so they will run only after receiving a "launch enable" message over the network. To launch copies of modified programs from a local hard disk, each user must have a "network pass," which is installed as a Startup document (INIT) in the user's system folder.

"If the maximum number of users allowed by the site license is using the program simultaneously, KeyServer will not give access to a prospective user. Instead, it passes a message that "All licensed copies are currently in use." When the program is freed, KeyServer returns a pop-up message to the prospective user, indicating that a launch is possible.

"KeyServer also allows network administrators to monitor current software access and generates a usage log, which can be used to negotiate or renegotiate site licenses with vendors, Devlin said. Several large vendors have expressed interest in the program, he added.

"It allows us to make a wide variety of software available without having to put a lot of money down for a site license on a bet that the program will be used," said Larry Levine, director of user services for the more than 5,000 Macintoshes on-line at Dartmouth. "We can freely distribute copies of programs without giving away control of their use."

"KeyServer differs from other Macintosh software management programs

because "Only the command to launch comes over the network," Devlin said. "The programs reside on the user's hard disk, cutting down on network traffic tremendously."

"KeyServer also allows the administrator to turn access to a program on or off for any length of time or to shut off access to old versions of software. The program does not require a dedicated server.

"Devlin is currently beta testing KeyServer at industry sites and negotiating licensing agreements with vendors. Through his company, Sassafras, Devlin hopes to have shrink-wrapped versions ready by summer. Though pricing has not been set, Devlin said it will be tied to the number of nodes per network."

A/UX: Problem Printing to ImageWriter from Mac OS (9/94)

I am running A/UX on a Macintosh IIcx. If I switch from A/UX to the Macintosh OS and try to print from a Macintosh application to the ImageWriter (connected via the printer port) the system won't print.

This article has been archived and is no longer updated by Apple.
If the system prints in A/UX but not in Macintosh OS, make sure that the direct, serial-printer driver for the ImageWriter is installed and configured properly.

If the printer does not print in A/UX either, we know of a problem when the printer is directly connected to the PRINTER port under either mac32 or mac24 environment (print from a Macintosh application). However, there is no problem on the direct connect MODEM port.

AppleShare PC: How to Print Color

Is it possible to print to a color printer through AppleShare PC? I am running a PS/2 with AppleShare PC 2.01, Windows 3.0, and Paintbrush from Windows connected to an NEC Colormate printer. If I configure the Paintbrush from Windows to print black and white, I can get a printout, but it doesn't work in color mode.

This article has been archived and is no longer updated by Apple.
As you know, the two types of printing that AppleShare PC supports are PostScript and Epson LQ2500 emulation. The PostScript mode assumes your application knows how to communicate correctly using PostScript and just passes the data to the printer without modification. This is called pass-through mode.

Epson LQ2500 emulation works a bit differently, in that AppleShare PC must translate the plain text and Epson printer control codes into text and codes for the printer being used; PostScript LaserWriters and ImageWriters are supported.

In the case of LaserWriter Epson emulation, an Epson emulation dictionary is downloaded at the start of each job. Once this is done, the print data is sent to the emulation dictionary for interpretation and printing. Because ImageWriters have essentially no processing abilities, they require AppleShare PC to do all the translation for them. Unfortunately, no color emulation features are provided in either mode.

The only way we can think of to get color printing from AppleShare PC would be to use a color PostScript printer with software that supported it. Since AppleShare PC just passes the PostScript print data to the printer, it will let any PostScript data, color commands included, be sent.

VAX/VMS: How to Set Up Dial-Up Port for DAL

What is the configuration on MicroVAX 3100 for setting up remote login through a modem?

I need dial into the VAX at my office from a customer site to demo Data Access Language. I have tried to set up terminal TTA2 as remote terminal without success.

This article has been archived and is no longer updated by Apple.
The procedure to set up a dial-up port is the same on VAX/VMS operating system, independent of what processor you have. The difference is the name of the terminal port you are going to use. For the process to work, the terminal port must support modem control.

On the MicroVAX 3100, terminal port TTA2 supports modem control. The following command should work:

$ SET TERMINAL/PERMANENT/DEVICE=VT100/MODEM/HANGUP/SPEED=2400 TTA2:

You may substitute the device name and the speed to whatever values you are using.

Also, make sure that the cable to the modem has the correct pins wired to support modem signals. One such modem cable is the Digital BC22E-xx where xx is the cable length in feet. It is a round, 16-wire, fully shielded, EIA-232-C/CCITT V.28, male-to-female molded connectors cable for connection of asynchronous modems.

If after trying this solution, it still does not work, you might want to have Digital Field Service check to see if your terminal port is bad.

IBM 8209/AppleTalk: Support Alert Information

IBM has a relatively new product, model 8209, that is a media access control (MAC) sub-layer bridge. Most likely encountered in a Token-Ring to Token-Ring bridging configuration, it also can be configured for Token Ring to Ethernet. Do you have any details?

This article has been archived and is no longer updated by Apple.
We recently had the opportunity of observing/troubleshooting such an environment involving an 8209, an IBM mainframe on Token Ring supporting TCP/IP, Macintoshes running both Phase 1 and Phase 2 AppleTalk on Ethernet, Macintoshes on Token Ring, and a variety of TCP/IP hosts on Ethernet. This leads to several interesting discoveries.

IBM 8209 and AppleTalk

Ideally, with the 8209 providing Token-Ring-to-Ethernet bridging services, Macintoshes on both transports would see the bridged network as a single logical network. Unfortunately, for a number of reasons, this is not true.

The first problem stems from the 8209's generosity in forwarding all datalink (MAC) broadcasts and multicasts. If you are running ANY Phase 1 EtherTalk, adding an 8209 into the net automatically generates Phase 1 TokenTalk. This is useless traffic, because the TokenTalk drivers expect Phase 2 protocols. As far as we can tell, it is not dangerous traffic--it is safely ignored by all nodes. But it does take up bandwidth, and if the Phase 1 Ethernet is large and has many routers, there can be significant broadcast traffic forwarded onto the Token Ring.

The answer here would be to filter Phase 1 EtherTalk at the 8209.

Token Ring and Ethernet do not agree on the order of bits. So, the 8209 flips the bits of the (MAC) datalink-level addresses when it forwards the packets. Normally, this affects only the destination and source addresses in the packet header. However, address resolution protocols like TCP/IP ARP and AppleTalk's AARP also carry MAC-level addresses as a part of their data portion of the packet.

The 8209 is specially programmed to look for TCP's ARP and to go down inside the data, flipping the bits of the embedded MAC address. Later, when a Token Ring host wants to talk with an Ethernet node, it uses the flipped version of the MAC address, which, when encountered by the 8209, is flipped back and thus delivered correctly.

The 8209 is NOT specially programmed to assist AARP. Thus, the AARP address is stored in the Token Ring AppleTalk node in its "unflipped" form. Then, should it be used later to address a packet, the 8209 will flip the bits when forwarding back to Ethernet. Now, the packet is incorrectly addressed, and cannot be delivered.

The long and short of this is that when using an IBM 8209 to bridge Token Ring and Ethernet, AppleTalk nodes on the ring and Ethernet cannot communicate, because they can never AARP correctly.

Curiously, if the Token Ring is used only as a backbone, and a Macintosh on Ethernet wants to talk to a Macintosh on another Ethernet, with both Ethernets attached by 8209s, this connection will work. In fact, as long as you go through an even number (2,4,6,8...) of 8209 bridges, connection is possible. When there is an odd number, connection will fail. Note that this makes some extremely bizarre network configurations possible, like a system of alternating Token Rings and Ethernets connected by 8209s, where:

* All the Ethernets would have AppleTalk connectivity.

* All the Token Rings would have AppleTalk connectivity.

* The rings and Enets would have AppleTalk connectivity between them.

You may remember that under AppleTalk Phase 2, Apple uses multicast addressing for all protocol "overhead" packets, like RTMPs, NBPs, and ZIPs. You may also recall that Apple has a range of 254 addresses used in Ethernet and 19 (different) addresses in Token Ring available for multicasts.

The fact that we use different ranges of addresses (in addition to the bit flipping described above) ensures that AppleTalk nodes cannot interoperate across an 8209 bridging Ethernet and Token Ring. Just look at the boot process.

A node begins by AARP'ing for a protocol address (multicast). This AARP is forwarded by the 8209, but because the bits are flipped, a response to the AARP probe would be lost on the return trip. So, the node assumes that its protocol address is unique, and then proceeds to check for a router by multicasting (protocol broadcasting) a ZIP GetNetInfo request. If there is an AppleTalk router present on my cable (whether we are on Ethernet or Token Ring), we are okay. The router hears my request, provides the needed information about the cable, and I re-AARP if necessary.

However, if the router is on the other side of the 8209, the multicast is forwarded. Even if the bit-flipping wasn't a problem (say, if IBM were to change the 8209 software to support AARP), it will still not make connection with the router, because a TokenTalk router expects multicast addresses in a different range than a EtherTalk node can send, and vice versa.

The only answer is to use an AppleTalk router, which manages protocol and zone multicast addresses for each data link appropriately.

In short, AppleTalk and 8209s don't mix. Don't use bridging strategies between AppleTalk Token Ring and Ethernet networks.

There are additional problems with 8209 and AppleTalk described in a separate article "IBM 8209/MacTCP: Support Alert Information."

Pascal: External references

This article has been archived and is no longer updated by Apple.
Apple Pascal may only "externally" link assembly routines. However, Pascal procedures compiled seperately can be placed into a library unit and accessed with the USES command.

Assembly code may also be placed into library units, provided it's called from the Pascal level. To do so: assemble the code file(s) and create a Pascal unit which refers to each .PROC and .FUNC of the code as EXTERNAL. To create an intrinsic unit containing assembly code, link the external references to the compiled P-code unit structure, then install this completed unit in the System.library file on your boot disk.

Since the regular units which reference assembly code are not linked prior to installing the library file, install the unlinked Pascal units in the System.library or in your own library file to keep these assembly code file(s) on hand. Link the assembly routines into the final code file when you link the host program with this regular unit.

VGA Compatibility

To connect a VGA monitor to the Macintosh LC or LC II video port, a cable with the following configuration is required. Third-party cable vendors should have these cables available for purchase.

A few issues to remember when connecting VGA monitors to the Macintosh LC or LC II:

* VGA monitors may have variances when purchased from different VGA monitor vendors. It is suggested that a particular monitor be tested for

compatibility with the Macintosh LC or LC II before making a purchase decision.

* VGA monitors from different vendors have different image quality specifications. There may be significant differences between the Apple logo monitors and the VGA monitors. A side-by-side review of the monitors should be done before deciding which monitor to buy.

* When a VGA monitor is connected as described above, the resolution is 640 x 480. The bit-depth supported depends on the amount of VRAM installed. If the Macintosh LC 256K VRAM SIMM is installed, 4-bit color (16 colors) is supported. With the Macintosh LC 512K VRAM SIMM installed, 8-bit color (256 colors) is supported.

AppleTalk Phase 2: Upgrade Utility

What is the AppleTalk Phase 2 Upgrade Utility? What does it do?

This article has been archived and is no longer updated by Apple.
The AppleTalk Phase 2 Upgrade Utility makes it possible for AppleTalk Phase 1 routers to operate concurrently in an Internet with the AppleTalk Internet Router. The AppleTalk Phase 2 Upgrade Utility is an INIT that is installed in the System Folder of the Macintosh running the AppleTalk Internet Router software.

Why the AppleTalk Phase 2 Upgrade Utility Is Necessary

The AppleTalk Internet Router sends out AppleTalk Phase 2-style Routing Table Maintenance Protocol (RTMP), Name Binding Protocol (NBP), and Zone Information Protocol (ZIP) packets. AppleTalk Phase 1 routers cannot interpret the data within these packets.

With the AppleTalk Phase 2 Upgrade Utility installed, any RTMP, NBP, or ZIP packet about to be sent out over a cable with an AppleTalk Phase 1 router on it, will be sent as an AppleTalk Phase 2-style packet and will be converted by the AppleTalk Phase 2 Upgrade Utility and sent out as an AppleTalk Phase 1-style packet as well.

Note: Only RTMP, NBP, and ZIP packets are converted to AppleTalk Phase 1-style packets. No other packets types need to be converted.

The AppleTalk Phase 2 Upgrade Utility also makes it possible for the AppleTalk Internet Router to receive AppleTalk Phase 1-style RTMP, NBP, and ZIP packets. When the AppleTalk Phase 2 Upgrade Utility INIT is installed, it throws a switch in the AppleTalk Internet Router that lets the router accept and process AppleTalk Phase-1-style RTMP, NBP, and ZIP packets. The AppleTalk Phase 2 Upgrade Utility does not convert these packets. The AppleTalk Internet Router has code built into it that lets it interpret these packets properly.

What the AppleTalk Phase 2 Upgrade Utility Does Not Do

It does not convert all outgoing AppleTalk Phase 2 packets to AppleTalk Phase 1 packets. This is not necessary--only RTMP, NBP, and ZIP packets need to be converted.

The AppleTalk Phase 2 Upgrade Utility does not work with any third-party router; it works only with the AppleTalk Internet Router.

System 4.0/Finder 5.4: Alarm Setting Won‘t Stay On (9/95)

Every time I turn off my Mac Plus I lose the alarm clock setting. I am running System 4.0. Why does this happen?

This article has been archived and is no longer updated by Apple.
In a Macintosh Plus with System 4.0 and Finder 5.4, a set alarm clock functions properly as long as system power stays on. If the system is powered down and back up again, a quick check of the alarm clock reveals that the switch to the alarm clock is turned off.

This does not occur under the previous system software, System 3.2 and Finder 5.3. You will need to upgrade to a more current version of the system software or revert to the previous version to correct this problem.

A/UX 2.0: "Header File" Problem/Fix

I've encountered a compilation problem recently while porting a program (tcsh, from OSU) to the A/UX 2.0 environment. The problem seems to be that some of the system's header files aren't compiling properly. The sample code below demonstrates the problem I've experienced:

```
------------------------
/* test file, called tsts.c */

/* these are well-knowns that should work */
#include <sys/errno.h>
#include <stdio.h>

/* these don't work */
#include <sys/stat.h>
#include <sys/times.h>

main()
{

}
```

Now, take a look at what I did. On the first try, I used the command:

cc tsts.c

Here is the output:

```
"/usr/include/sys/stat.h", line 48: syntax error
"/usr/include/sys/stat.h", line 48: cannot recover from earlier errors:
goodbye!
```

On the second try, I used the command:

gcc tsts.c

Here is the output:

```
In file included from tsts.c:7:
/usr/include/sys/stat.h:48: parse error before `dev_t'
/usr/include/sys/stat.h:54: parse error before `dev_t'
/usr/include/sys/stat.h:64: parse error before `time_t'
In file included from tsts.c:8:
/usr/include/sys/times.h:29: parse error before `time_t'
```

Is there something amiss? I'm assuming the header files stat.h and times.h are identical to the header files available to you, so I've not copied them here.

This article has been archived and is no longer updated by Apple.

Put the following line before the #include <sys/stat.h> line. It should work, because some of the declarations in <sys/stat.h> were defined in <sys/types.h>.

```

Macintosh Portable: Dialing an Internal Modem

I am having problems using the Communications Toolbox, the Apple Modem Tool, and MacTerminal 3.0 on a Macintosh Portable. I am unable to establish connection to the Macintosh Portable's internal modem when I select "Open Connection" from the menu. However, when I leave the phone number field blank in the Apple Modem Tool's connection dialog box, I have no problems establishing a connection with the internal modem.

We suspect that your problem is caused by an improper setting in the connection dialog box of the Apple Modem Tool. Be sure you've selected the Macintosh Portable Data Modem 2400 in the "Modem:" popup menu at the bottom of the "Connection Settings" dialog box. When we chose a different modem type under this popup menu, we duplicated the problem you describe.

BAD 1.1 INIT Is Shareware

Logging onto AppleLink (with "reseller privileges") I notice the INIT BAD 1.1 is located under the User Groups icon (path: Product Questions and Answers/ Macintosh/ System Software). I have done a fairly detailed analysis of this INIT and I believe it could be useful to some of my customers.

Can I freely distribute this INIT to my resellers? Can my resellers freely distribute this to their end-users? I assume the answer is "Yes." Otherwise, I would not expect it under the User Group icon.

This article has been archived and is no longer updated by Apple.
BAD 1.1 is not an Apple product. Rather, it is a shareware program by Giuseppe Carnevale from Italy. As such, it can be freely copied and distributed, but should not be distributed as an Apple-supported program. If you do distribute it, it must be made clear that the author expects payment for each station where it is actively used.

More information can be obtained from the program's documentation, or by opening the program's "About" window. This is done as follows:

1) With BAD active, select an already-formatted disk.

2) Select Erase Disk from the Finder's Special menu. Instead of the normal initialization dialog, you should be presented with BAD's own "The disk '<name>' is already initialized." dialog.

3) Click the BAD disk icon at the left of the dialog window and the author's address will appear.

Macintosh: Printing to DEC ScriptPrinter LN03R

Do you know of a way to print from a Macintosh to a LN03R? I have a driver that supports modem communication, but I need something that supports a direct serial connection.

This article has been archived and is no longer updated by Apple.
To our knowledge, there is no driver that lets a Macintosh print directly to the Digital ScriptPrinter LN03R. One alternative is to print to a disk file from the application and then send the file to the printer using a terminal emulation program. With the correct cable, you can communicate to the printer using a terminal emulation program like MacTerminal over the serial port. Needless to say, this is not very convenient.

Another alternative is to use the printer on the network:

* DEC LanWORKS for Macintosh offers this capability. The service is called VAXshare Print Server, and it supports Digital's LPS20, LPS40, ScriptPrinter LN03R, and Apple's LaserWriter, LaserWriter Plus, LaserWriter IINT, and LaserWriter IINTX.

* With Alisa Digital Printer Support System (ADP), an option for AlisaTalk for VAX/VMS, Macintosh users can print to Digital PostScript devices like the LN03R ScriptPrinter and the PrintServer 40. The Digital PostScript device looks like an Apple LaserWriter to the Macintosh user.

ADP makes use of VMS system queuing and printing. Features include forms and paper type control, optional job flag and trailer pages for job identification, paper tray selection, and support for the Adobe system typeface pack. Once VMS receiver process handles all Macintosh users, a new process for each job is not necessary. The software uses standard Digital Print symbionts and automatically loads the Laser Prep dictionary at the front of each Macintosh job that is submitted.

* PacerPrint from Pacer Software, Inc., offers similar features. For more information on Alisa Digital Printer support system or PacerPrint, search the Technical Info Library using keyword "Alisa" or "PACER."

Novell Token Ring Network: Access from Macintosh

Can I access Novell Token Ring network and its server using the existing Apple Token Ring card and also Netware for Macintosh?

This article has been archived and is no longer updated by Apple.
The Novell TokenTalk support is orderable and was delivered in September 1990. This is a new version of VAP (Value-Added Process) that supports AFP (Apple Filing Protocol) 2.0 and TokenTalk.

All Netware operating systems provide an internal router that lets a Netware server connect to four different networks. No additional software is required. Note that the routing service can also be moved out of the server and into a non-dedicated workstation.

Macintosh, DOS, and OS/2 workstations can share data and resources. Macintosh users should see information stored on the network server as icons. Other workstations on the network (PCs running DOS, OS/2, or Windows/386) should see the folders and file icons from the Macintosh listed as directories and subdirectories in their workstation formats.

DOS, OS/2, and Macintosh users can share Apple LaserWriters and other Apple printers. Using an E-mail package that supports Netware Message Handling Service (MHS), the back-end store-and-forward messaging server, you can send E-mail messages, text, data, and binary files between different LANs and between wide-area networks.

For contact information, search the Technical Info library under "Novell" and the Enhancement Products Division of the Netware Products Division.

EtherTalk NB and EtherLink NB: Revision Numbers

I understand that AppleTalk Phase 2 and the Macintosh IIci require Rev. J or Rev. K of the EtherTalk NB Card, while the Macintosh IIfx requires the EtherTalk NB Card Rev. L (Rev. L is not merely an upgrade to a Rev. J or Rev. K). If this is the case, why are brand new 3Com EtherLink NB Cards (with 1990 labels on their diskettes) Rev. B?

This article has been archived and is no longer updated by Apple.
3Com uses a different assembly numbering scheme for the Ethernet cards that they sell under their own label, as the 3Com EtherLink NB Card, than it does for the Ethernet cards Apple buys from 3Com and sells under its own (Apple) label as the Apple EtherTalk NB Card. The chart below shows how the 3Com EtherLink NB Cards relate to the Apple EtherTalk NB Cards:

Apple EtherTalk NB Card Assembly Number	3Com EtherLink NB Card Assembly Number

LaserWriter IINTX and Hard Disk "Space Available"

I have a question concerning hard-drive formatting when an Apple hard drive is attached to a LaserWriter IINTX.

It seems that you never get the same "space available" amount when formatting two same-sized hard drives. This is true even if you reformat the same hard drive more than once. The second time you format the drive, you may get more, or even less, space available. The third time you format it, you may get an entirely different number, sometimes more, sometimes less.

This article has been archived and is no longer updated by Apple.
We tried to duplicate the problem you described on a LaserWriter IINTX with the old 1.0 ROMs and a LaserWriter IINTX with the new 3.0 ROMs. For the LaserWriter with the 1.0 ROMs, we used the "LaserWriter Font Utility 1.0" program. For the LaserWriter with the 3.0 ROMs we used the "LaserWriter Font Utility 2.0" program.

In both cases, the LaserWriter IINTX printers reported that the hard disk had the same amount of total space and the same amount of space available. Could it be that the hard disk may have some problem with it? Try a different hard disk. Also, try a different LaserWriter.

We wrote the following PostScript program that returns information on the total space and the total free space of the hard disk connected to a LaserWriter IINTX:

Macintosh IIsi, Macintosh LC: Power Limits & Thermal Shutdown

What can you tell me about the Macintosh LC and the Macintosh IIsi concerning their power supplies and power ratings for their slots? At what temperature will the thermal shutdown circuits shut down the power supply?

This article has been archived and is no longer updated by Apple.
The power limit for the NuBus slot in the Macintosh IIsi is 15 watts (the same for any Macintosh II NuBus slot). The power limit for the Direct slot in the Macintosh LC is 4 watts.

Both the Macintosh LC and the Macintosh IIsi have a thermal shutdown circuit which will shut down the power supply in the event of possible overheating from excess power draw. The maximum operating temperature is approximately 105 degrees Farenheit.

The Macintosh LC will cycle off-and-on until the temperature reaches a safe operating level (It will make a motorboating sound). At that point, it will resume operation.

In the event of overheating, the Macintosh IIsi acts as if you had chosen Shut Down and will let you power up it up again only when the temperature drops to a safe level. Pressing the keyboard Power On key has no effect in this condition. If the Macintosh IIsi power switch is locked on, it will behave like the Macintosh LC.

A/UX 2.0: Fitting It on a 40MB Disk

Can a usable A/UX 2.0 be squeezed onto a 40MB disk? Is there a suggested configuration or list of directories to remove to "shoehorn" it into that size? What is the minimum, suggested swap space?

This article has been archived and is no longer updated by Apple.

The following is a list of "du" (disk usage) from the A/UX 2.0 Root system, which tells the size of each directory in 512-byte blocks.

```
        /*UNIX*       2900
        /bin          5122
        /dev            38
        /etc         12874
        /shlib         458
        /usr/bin      8926
        /usr/adm        28
        /usr/catman   6218
        /usr/dict      410
        /usr/etc      1928
        /usr/games    1400
        /usr/include  2882
        /usr/lib     12394
        /usr/spool     448
        /usr/ucb      3296
        /lib          4464
        /mac/bin      4594
        /mac/lib      7344
        /mac/src       504
        /mac/sys      6238
        -------------------
        Total       82,466 blocks
```

If A/UX 2.0 is purely used for NFS purposes only, it might be possible to squeeze the size and fit it on a 40MB disk. However, it might take some time to go through each of the files and/or directories and determine which to keep or to remove.

In general, a lot of files and/or directories like /usr/catman, /usr/games, /usr/dict, /mac/src, may be removed.

The default Swap size in A/UX 2.0 is about 18MB. 14MB was the default swap size used in A/UX 1.1.1 and before. This increase is mainly for A/UX 2.0 MultiFinder activities. If you do not have many Macintosh applications and/or specifically A/UX applications like C language compilations running on the system, it may be reduced to below 10MB. Furthermore, if you have plenty of physical RAM, 16MB or 32MB for example, you may reduce more swap space.

Again, this is still the "It depends..." type of question. We can't give an exact number on the size of Swap area and also, which files/directories should be kept or removed. You probably need to play the "try and error" game to knock the system below 40MB.

Macintosh IIsi: EtherPort Compatibility Issues

Are there any known compatibility problems with the Kinetics/Excelan/Novell EtherPort II cards and the Macintosh IIsi?

Has this card has been tested, and, if so, could you provide the hardware and software versions, and the results of your test? If not, have any other issues surfaced?

This article has been archived and is no longer updated by Apple.
This is what we learned from Novell: Any software incompatibilities would reveal problems between the driver and the operating system. The card itself would not be the cause of a software conflict.

If the driver installer disk has an old System folder, boot from the System Tools disk, then put in the EtherPort Installer disk and run the Installer as you would normally. You'll have to do some disk swapping, but it should work. Past the OS question, there should be no other software problems.

Because the Macintosh IIsi is rather new, we have not been able to verify that there are NO incompatibilities. When Shiva Corporation bought the EtherPort line of Macintosh-to-Ethernet interface boards from Novell, Inc. (in December 1990), they made a commitment to support the EtherPort and driver with all of the appropriate Macintosh computers. So, in the future, they might be able to provide more detailed information on the compatibility issues concerning the newer Macintoshes.

My guess is that Shiva is making a very safe statement saying that because the EtherPort II has not been thoroughly tested with the Macintosh IIsi or the Macintosh LC, they cannot (and neither can we) say the card will work with those computers. So, at this point customers just have to try the combination to see if it works. Probably they are also saying that if some problem is found, they will release new hardware and/or software to provide solutions.

Pascal: Keypress function

This article has been archived and is no longer updated by Apple.
Keypress is a commonly used function residing in the Applestuff unit. If it's the only routine needed from this unit, it is more efficient to refer to the routine alone without loading the entire unit.

The following listing of the function Keypress can be assembled for linking to your host program as an "external" function. Follow the instructions that accompany the examples shown on pp. 136-182 of the Pascal Operating System Reference Manual.

```

The sample program below illustrates the use of Keypress as an externally linked routine. Follow the instructions given on pp. 136-182 of the Pascal Operating System Reference Manual for assembling and linking external code.

```

MacTCP: RFC Conformance

I'd like to know what RFCs and MIL-STDs MacTCP follows.

This article has been archived and is no longer updated by Apple.
MacTCP is a complete implementation of the TCP/IP protocol suite and is fully compliant with the appropriate MIL-STDs (1777 and 1778) and RFCs (768, 791, 792, 793, 826, 894, 950, 1034, and 1035) and comprises TCP, UDP, IP, ICMP, DNR and for broadcast networks, ARP. The product will operate with gateways that comply with RFC 1009.

Internet Router: How to Save Zone Name Changes

I tried to change the name of one our LocalTalk segments. After the change was made, I saved the changes in the Internet router. Then, I re-loaded the router, but the router would not accept the change of name. It kept on referring to the old name of the zone. There were no other routers loaded at the time. The router let me change all the other zone names including EtherTalk and TokenTalk zones. This is a total Phase 2 network.

This article has been archived and is no longer updated by Apple.
There is no reason for the router to exhibit the symptoms you described. When you change a non-extended networks zone name you must follow these steps:

1) Set the current status to off.

2) Click the Zone name box for the network you want to change.

3) Select the zone name from the zone names list, there should be only one for non-extended networks.

4) Click the Delete button to remove the zone name from the list.

5) Type the new zone name into text box and click on the Add button.

6) Save the changes and restart the Macintosh.

It's easy to open the dialog box to change the zone name. Select the old name, change it in the text box and click Done without ever deleting the old zone name from the list. This causes the zone name for the network to not be updated, and the old zone name would be used the next time the router is loaded.

The only way this could fail is if there is another router that still has the old zone name or a different zone name configured for this network. The newly-configured router would then fail with a conflicting zone name message the next time it loads. It would not fall back to the old zone name, but would fail and ask you to reconfigure and restart.

HyperCard 2.0: Print Report Procedure

I have switched over to HyperCard 2.0. In earlier versions, I used the "column format" in which you could drag the dashed separation lines to print out a report. How do I do this in HyperCard 2.0?

This article has been archived and is no longer updated by Apple.
The Print Report functions of HyperCard 2.0 has many more features than previous version. Unfortunately, laying out a report the first time requires more work than before. One of the main differences that may be confusing you is that you must specify the items to print by using menu items that come up when you select Print Report. These items are no longer in the Print Report's dialog box as in previous versions.

Creating a report template is described in the "HyperCard Reference" manual in the Chapter on Printing (presently chapter 7, page 380).

In brief:

1) Choose Print Report.

2) Choose New Report from the Reports menu; name your report.

3) In the Print Report dialog box, set up the layout for your report. Resize cells, add a header if desired, and set your options.

4) Choose Report Items from the Edit menu.

5) Choose new Item from the Item menu; while the item is selected, resize and reposition if desired.

6) While the item is selected (step 5), choose Item Info from the Items menu (or double-click it).

7) Specify the contents of the item, and its characteristics like font and size, alignment, and so on.

8) Click OK.

9) Repeat steps 5 through 8 if desired.

10) When you've added all of the items you want, click OK to return to the Print Report dialog box.

11) Click Print.

Many more options are available than what is covered here. However, this should be a reasonable primer on the Print Report function. HyperCard 2.0 lets you create and save up to 16 reports per stack, and is much more capable and versatile that earlier versions.

Macintosh LC: RAM Configurations and Limits

What is the maximum amount of memory possible in the Macintosh LC? Is 10MB an absolute limit? Will a future Macintosh LC be able to use 34MB with the addition of two 16MB SIMMs?

This article has been archived and is no longer updated by Apple.
There is a limit of 10MB of RAM on the Macintosh LC when running under System 7. It will not be possible to use 16M SIMMs to achieve 34MB. This is because the memory map for the Macintosh LC reserves only 10MB of address space for RAM, regardless of if it is in 24-bit mode or 32-bit mode. The memory map is as follows:

Function	24-bit mode	32-bit mode
RAM	$00 0000-$9F FFFF	$0000 0000-$009F FFFF
ROM	$A0 0000-$DF FFFF	$40A0 0000-$40DF FFFF
Expansion space	$E0 0000-$EF FFFF	$FE00 0000-$FEFF FFFF
I/O space	$F0 0000-$FF FFFF	$50F0 0000-$50FF FFFF
VRAM	$FC 0000-$FF FFFF	$50FC 0000-$50FF FFFF

It is also not possible to use 256K or 512K SIMMs. The possible RAM configurations, using 1MB, 2MB, and 4MB SIMMs, for the Macintosh LC are:

2MB -- soldered on the motherboard
4MB -- add two 1Mbit SIMMs in each of the SIMM connectors
6MB -- add two 2Mbit SIMMs in each of the SIMM connectors
10MB -- add two 4Mbit SIMMs in each of the SIMM connectors

The Macintosh LC requires 100ns or faster SIMMs.

Apple Scanner: 8-Pin Port Is Non-Functional

I need information regarding the 8-Pin port that is next to SCSI port on the Apple Scanner. What is it for? (The icon indicates LocalTalk.) How can developers find out more about implementing it?

This article has been archived and is no longer updated by Apple.

The port was originally intended to allow the scanner to be connected to the network. This capability was eventually dropped, so the port is essentially connected to nothing. There is no way for developers to use the port.

3270 Async Terminal Emulation and File Transfer Needed

I am looking for a package to duplicate the capabilities of IBM's FT Term. It runs on PCs and includes 3270 terminal emulation running over async lines with support for 5 DFT sessions and file transfer on a single call. Does any package for the Macintosh duplicate this functionality?

This article has been archived and is no longer updated by Apple.
The PC/HOST File Transfer and Terminal Emulator Program (FTTERM) provides 3270, DEC VT100, DEC VT220 and 3101 terminal emulators, along with 3270 and ASCII file transfer capabilities. In addition, FTTERM Version 2.1 expands its connectivity options to let an IBM Personal Computer or Personal System/2 operate on an IBM Token-Ring Network or a Broadband IBM PC Network local area network (LAN).

When operating on the LAN, it uses the Enhanced Bios Interface Programs and communicates through the IBM Local Area Network Asynchronous Connection Server Program (LANACS), to connect to ASCII Hosts, dial Information Providers, and obtain the use of Protocol Converters to allow access to IBM hosts. File transfer is supported to ASCII hosts or IBM Hosts. FTTERM Version 2.1 also supports an asynchronous connection for IBM Professional Office System (PROFS) (TM) Applications Support Feature (PASF) Version 2.2.2 (non-Token-Ring LAN configurations) and GDDM-PCLK 1.1 through the FTHLLAPI (FTTERM High Level Language Application Program Interface) facility.

The actual session management is controlled at the 3174 and not by FTTERM.DFT emulators like Personal Communications/3270 control sessions within the PC. In previous microcode levels, an ASCII display connected to the Async Emulation Adapter (AEA) was able to have only two sessions, although Coax-type CUT terminals were allowed up to 5 sessions. Microcode level B2 has extended that support to ASCII displays and the AEA.

We have not found a similar application with these functions on the Macintosh. Simware offers a multi-session 3270 terminal emulators and file transfer over asynchronous lines, if used in conjunction with their host software Sim3278 VM or VTAM. RELAY provides only file transfer over async lines to a mainframe running RELAY Communications' RELAY/VM or RELAY/TSO. MacBLAST software for IBM mainframe also transfers text or binary files via async ports or protocol converters. DCA (formerly Avatar) MacMainFrame DX provides only single-session terminal emulation and file transfer over asynchronous lines.

To locate a vendor's address and phone numbers, use vendor name as a search string.

Pascal: SCAN function

This article has been archived and is no longer updated by Apple.
The Pascal SCAN function scans a range of memory, searching for a specified target. This function takes the form:

SCAN (Limit, PEXPR, Source)

where Limit is the number of bytes scanned, PEXPR defines the target and Source is the variable. The Pascal Language Manual on pp. 51-52 describe this function in greater detail.

Use SCAN on any variable except file types. When scanning string S, for example, specify Source as S[1] to avoid having SCAN look at the length parameter stored in S[0], which usually yields an erroneous value.

Apple II SCSI Card: ROM Upgrade (2/97)

This article describes how to obtain the Apple II SCSI Card ROM upgrade.

This article has been archived and is no longer updated by Apple.

There is a repair extension that covers your on this. Contact your dealer about getting the cards upgraded. Here is the information the dealer will need:

SCSI INTERFACE CARD IIE & IIGS ROM UPGRADE--OLC123
(Announced March 88)

Users who upgrade to Apple IIGS Operating System Version 4.0 or greater must use the latest revisions of both the SCSI Interface Card and the ProFile Interface Card. You can determine the latest version of these interface cards by checking the part number of their ROM. As of March 88, ROM part number 341-0437, Revision A, is the latest version of the SCSI Interface Card. All SCSI and ProFile Interface Cards now shipped by Apple are the latest revisions.

Apple has revised the ROM on the Apple II SCSI Interface Card to make the card compatible with the Apple-CD SC and the Apple IIGS Operating System. When other products requiring the new ROM are introduced, you will be notified by a Service mailing. The ROM on the card can be identified by the new part number, 341-0437. All Service Stock and Finished Goods inventory has been upgraded to the new ROM.

Some Macintosh Applications Ignore Inserted Diskettes

With Persuasion or PowerPoint (or both of them) open, when I insert a new unformatted diskette, there is no dialog box asking to initialize the diskette. Even after I quit from the application(s), the system does not acknowledge that a diskette has been inserted. One has to eject the diskette and re-insert it before the initialize dialog box pops up. This anomaly occurs even under System Software 6.0.7. It does not help to clear the System of INITs or to work under Finder instead of MultiFinder. What could be the reason for it?
This article has been archived and is no longer updated by Apple.
This is not really an anomaly. We will try to explain why:

When a disk is inserted into a disk drive, a disk-inserted event is generated by the Event Manager. It is the responsibility of the application (the active application if MultiFinder is running) to respond to this event. Applications don't have to respond to all possible events. Some applications, like Persuasion and PowerPoint, completely ignore disk-inserted events.

The exception to this is when the SFPutFile or SFGetFile dialog is active for saving or retrieving files. Disk-inserted events are automatically handled when these dialogs are active. The only time this is a problem is when the disk inserted is a disk that must be formatted to be recognized by the system.

All it would take to support disk-inserted events (for initializing) in most applications is code, in the application's event loop, that looked something like this:

```
diskEvt:
IF HiWrd(myEvent.message) <> noErr THEN
BEGIN
SetPt(aPoint, $70, $50);
theError := DIBadMount(aPoint, myEvent.message);
END;
```

A/UX 2.0: Eschatology and dp

Here is my configuration:
* A/UX 2.0
* Macintosh IIcx
* 80MB hard drive
* Macintosh OS 6.0.5

Doing an installation on a SuperMac drive with

XP100
XP150
A/UX 2.0

sets up the partition sizes using the 4.1 manager for SuperMac (the size for each partition is stated in the manual). I do the initial installation which is the stand-alone shell, A/UX Startup.

While in the shell, I run the UNIX DP software. I use DP to designate the partitions as Root, User, Swap, and Eschatology. I quit DP and then follow the manual for installation. When the program gets to the Eschatology partition, I get a message that it will skip the Eschatology partition, because it cannot be found.

Doesn't the DP program assign the proper slice number for the Eschatology partition?

This article has been archived and is no longer updated by Apple.

```
The following are the standard A/UX file-system, partition names and slice numbers assigned when installing
A/UX 2.0:

     "A/UX Root"     slice 0
     "Swap"          slice 1
     "Eschatology 1"
     "Unreserved 1"  slice 3

There is no fixed slice number assigned to "Eschatology 1", but it was pnamed when copying essential files
into that partition during installation process. "Usr" will be assigned with slice 2, if it was customized as
a separate partition from the A/UX Root partition.

The problem is most likely the use of the name and the type of the "Eschatology" partition when you use "dp"
to customize the third-party hard drive.  The following is the printout for "Eschatology 1" partition from
"dp". Pay attention to the name ("Eschatology 1") and type ("EFS").

Memory Configurations: Other Desktop Macintosh

What are the memory configurations for desktop Macintosh computers?
This article has been archived and is no longer updated by Apple.
The tables in this article show the memory configurations for desktop Macintosh computers. For information about upgrading the memory in another Macintosh computer, refer to the following TIL articles:

- **Memory Configurations: Power Macintosh**
- **Memory Configurations: Servers**
- **Memory Configurations: Portables & PowerBook**

Note: The following computers are not 32-bit clean. They require the 32-bit System Enabler for System 7.1 or the MODE32 Version 7.5 for System 7.5.x in order to run in 32-bit mode and take advantage of more than 8 MB of physical RAM: Macintosh SE/30, II, IIx, and IIcx.

Note: Memory interleaving is supported in the Macintosh Quadra 800 and 650 computers when SIMMs are installed in pairs.

Graphtec MP3100: Connection to Macintosh

I am trying to connect a Graphtec MP3100 plotter to a Macintosh, but I don't have the right cable. Do you know what this cable should look like (from the 8-pin serial port on the Macintosh to the DB-25 port on the plotter)?

This article has been archived and is no longer updated by Apple.
The Graphtec plotter can be connected to a Macintosh 8-pin serial port using M0199; the Macintosh-to-ImageWriter cable (pn 590-0553).

Macintosh LC: VRAM Upgrade Procedure

How do you complete the VRAM Upgrade Installation for the Macintosh LC? The documentation in the Upgrade Kit says that the technician should consult the Macintosh Technical Procedures for information on how to complete the upgrade installation, yet there isn't anything in the Tech Procedures to cover this installation.

This article has been archived and is no longer updated by Apple.
Before you begin, familiarize yourself with the Take Apart section of Technical Procedures--especially those sections pertaining to safety and Electrostatic Discharge prevention.

When upgrading the Video RAM (VRAM) of the Macintosh LC, it is important to refer to the note on page 1.2 of the Technical Procedures for the Macintosh Family (Volume Two, Macintosh LC tab), which states that the 512K VRAM SIMM replaces rather than augments the 256K VRAM SIMM on the logic board.

For identification of which SIMM is the VRAM SIMM, you are encouraged to refer to the illustration in the same binder on page 1.4 or the illustrated parts list on page IPL.2, item number 21. The VRAM SIMM is located on the logic board immediately next to the system RAM SIMM connectors. The VRAM differs from system RAM by using a physically larger SIMM connector and more and denser signal leads.

The RAM exchange would be identical to the Macintosh Display Card Upgrade procedure (refer to page 2.10 of the Macintosh Family Cards tab in the Macintosh Family Technical Procedures, Volume Four), except that only one VRAM SIMM is required.

StyleWriter: Using it with the Macintosh Portable

The Apple StyleWriter and the Macintosh Portable appear to have similar power adapters. Can they be interchanged?

This article has been archived and is no longer updated by Apple.
Extreme care should be taken when using a StyleWriter with the Macintosh Portable.

The Apple StyleWriter and the Macintosh Portable have physically identical power adaptor connectors. However, they are NOT electically identical. If you connect a StyleWriter power adaptor (while unplugged from a wall outlet) to the Macintosh Portable, the 3.15 amp fuse inside the StyleWriter power adaptor blows.

The problem is that the Portable power adaptor is center positive, 7.5V, and the StyleWriter unit is center negative, 9.5V.

Pascal: TRUNC and ROUND functions

This article has been archived and is no longer updated by Apple.
The TRUNC and ROUND functions are available in Apple Pascal. The ROUND function is of the form I:=ROUND(R), where I is an integer and R is a real number.

TRUNC takes the form I:=TRUNC(R), where I is an integer and R is a real number, and I:=TRUNC(L), where L is a long integer. In all cases, integer values must be in the range -32767 to +32767; otherwise, a value range error is returned.

Although the compiler may accept other forms of these functions, these are the only legitimate forms according to UCSD definitions.

Japanese Macintosh Products: Support in the U.S.

Article Change History

09/22/92 - REVISED
* To include reseller referal phone number.
09/22/92 - UPDATED
* To include information on the Kanji TrueType product.

On April 23, 1991, Apple USA announced a program to sell and support Japanese-language Macintosh System Software in the United States. This is an extension of a program currently being piloted in Hawaii. To find a reseller for this product, call 1-800-882-8856.

This article has been archived and is no longer updated by Apple.
These Japanese products will be available only through a limited number of Apple-authorized dealers and VARS (Value Added Resellers). These resellers are required to have a Japanese-speaking System Engineer who has attended a special class for Japanese product support and who provides support before and after the sale. Inquires concerning these Japanese products should be directed only to these authorized dealerships.

The following products are being offered:

* The KanjiTalk Upgrade kit, which includes
- the KanjiTalk operating system version 6.0.7, and
- HyperCard-J version 2.0J ("lite" HyperCard localized in Japanese).

* Kanji TrueType - A Japanese font extension that allows high quality, low cost printing solution. It includes two complete fonts.

* HyperCard 2.0J, which includes Japanese manuals.

* The extended Kana character-based keyboard.

Price pages for these products will be available only to specially authorized resellers.

Service

Only Kanji-authorized resllers will be allowed to service Apple's Japanese systems.

Support

A special support program will handle the Japanese products. Customers will be supported by specially trained bilingual dealer System Engineers. These dealer SEs will escalate their questions to a third party vendor, in essence filling in the role of the Apple field Systems Engineer.

Japanese Macintosh System Software: Overview

Article Change History:

09/29/92 - REVIEWED
* For technical accuracy.

Could you please give me an overview of Japanese system software that is now available in the United States?

This article has been archived and is no longer updated by Apple.
The text resources and special features of Japanese Macintosh system software have been translated to fit the Japanese dates, sorting system, and so on. Otherwise, the Japanese system software works like Roman-alphabet system software, and troubleshooting is very similar.

On the other hand, Japanese system software must deal with a total of over 6800 characters in four different character sets. An INIT called KanjiTalk manages this large set; it takes keystrokes and converts them into Japanese. Along with this INIT, a variety of input modules, dictionaries, and fonts files are necessary to support KanjiTalk.

Japanese Macintosh 6.0 system software can be used on any Macintosh system with 2MB of RAM (a hard disk is strongly recommended). However, no special hardware is necessary. Although there is a localized version of the keyboard, KanjiTalk can accept input from a U.S. keyboard. In fact, the only difference between the U.S. keyboard and the Kana keyboard is the addition of the Kana characters silk-screened on the key caps.

Macintosh hardware products were originally made specifically for the Japanese market, with Kanji fonts in ROM. These products have been discontinued.

U.S. applications that abide by the Script Manager interface (TeachText, for example) generally work with Japanese Macintosh system software, but there is no guarantee of full functionality. It takes two bytes (not just one) to represent a Kanji character, and applications that don't take this into account typically don't work without some problems.

ImageWriter: Cleaning Guide Rails Solves Registration Problem

This article has been archived and is no longer updated by Apple.

As ImageWriters and wide-carriage ImageWriters become older, the lubricants used on the carriage rails tend to dry up and prevent the carriage assembly from moving freely during printing. This can lead to unacceptable horizontal print registration: columns of characters don't line up properly from one line to the next, and appear to be shifted anywhere from one dot to half a character.

When this happens, thoroughly clean both guide rails with a degreasing solution and lint free cloth, then lubricate them. Clean the rail all the way around, not just the surface area visible from the top.

System 7: How to Revert to System 6 after Installing System 7

How do I revert to System 6 after installing System 7?

This article has been archived and is no longer updated by Apple.
Before upgrading to System 7, back up your hard disk using any of backup and restore products available for the Macintosh. At a minimum, back up your System folder.

Please do not try to install System 6 over System 7. Instead, follow these steps:

1) To remove System 7 from your hard disk, boot from a System 6 "System Tools" floppy disk and drag the System 7 "System Folder" from your hard disk into the Trash can.

2) Restore your System 6 "System Folder" from a backup, or install from the System 6 "System Tools" floppy disk.

System 7: Sharing LaserWriters with System 6 Computers

Can users running System 7 and users running System 6 share the same LaserWriter? Does the 6.0 LaserWriter driver work with System 7?
This article has been archived and is no longer updated by Apple.
The System 7 printer drivers operate on Macintosh computers running System 6 and on Macintosh computers running System 7. When all computers printing to the same printer use System 7 printer drivers, they can compatibly share a printer.

You should upgrade System 6 Macintosh computers that are on a network with System 7 Macintosh computers to System 7 printer software. This will allow LaserWriter compatibility between both systems.

Early versions of the LaserWriter Drivers for System 7 were tested with all System 6 versions. Later LaserWriter Driver versions were only tested with System 6.0.8, and is the only System 6.x version now officially supported by Apple.

To install the LaserWriter 7 driver on a System 6 machine, follow the set of steps appropriate to your computer:

From floppy disks, follow these steps:

1) Insert the System 7 "Printing" disk (800K and 1.4MB). You do not need to boot from this disk. Place it in the drive of the currently running Macintosh you wish to update. This installation occurs "live" on your current system.

2) Double click the "Printer Update" icon.

3) Double click "Install". The System 7 printing software is now being installed on your system

4) Choose Quit. Your system has been updated to the System 7 printing software and is immediately ready to print in a System 7 environment.

Over a network, follow these steps:

1) Ask your network administrator where the "Printer Update" installer is located on your network and open that folder.

2) Locate and double click on the "Printer Update" icon.

3) Double Click "Install". The System 7 printing software is now being installed on your system.

4) Choose Quit. Your system has been updated to the System 7 printing software and is immediately ready to print in a System 7 environment.

After installation, open the Chooser and select the appropriate printer. If a dialog box appears asking if you want to initialize the printer, click "Yes". Make sure that all users on the network using this printer are running either System 7 or have updated their printing software to System 7.

Alternatively, you can simply drag the System 6 LaserWriter driver and the Laser Prep file to the trash. Then drag the System 7 LaserWriter driver to the System Folder.

System 7: Diagnosing System Bombs

I've installed System 7 and it bombs. What should I do?

This article has been archived and is no longer updated by Apple.
If your system bombs, proceed as follows:

1) Restart your Macintosh while holding down the Shift key, and release it when the desktop appears. This action causes most of your system extensions (INITs) and control panels not to load when the system boots. (Note: In System 7, INITs are referred to as "system extensions.") After you have removed your INITs and control panels, take each one, one-by-one, and drag it to the System Folder and restart. If the system bombs again, you will be able to tell which INIT, control panel, or combination of them is causing the crash.

2) Open your System folder and remove all of your extensions and control panels by placing them in a separate folder outside the System Folder. Examine the system extensions and verify that you are using the current version. If necessary, contact the product developer to determine which is the current version.

If your Macintosh computer still does not start up, continue to step 3.

3) Restart from one of the System 7 floppies. In the System 7 disk suite, the bootable floppy is the "Disk Tools" disk (both 800K and 1.4M).

4) Move any fonts, desk accessories, extensions, control panels, and preference files that you want to keep from the System Folder to another folder on your hard disk. Drag the remainder of the System Folder to the trash and empty the trash.

5) Do a "clean" install of the software by following the installation guidelines in your "Macintosh User's Guide."

If your Macintosh computer still does not start up, contact your dealer.

System 7: Virtual Memory and Third-party Accelerators

Article Change History

* For technical accuracy.

Can customers use the Virtual Memory feature of System 7, if they have third-party accelerators for the Macintosh Plus, SE, or Classic?

This article has been archived and is no longer updated by Apple.
No. The virtual memory feature of System 7 is available only on the Macintosh II family of computers that are equipped with a 68030 microprocessor or equivalent. System 7 Virtual Memory was written for the Macintosh II family (and more specifically, for the Macintosh II ROMs). Please contact the developer of your accelerator for additional information.

System 7: Compatibility of Third-Party Hard Disks

Are third-party hard disks compatible with System 7?
This article has been archived and is no longer updated by Apple.
Yes. Virtually all of the third-party hard disks tested by Apple are compatible with System 7.

However, you may run into issues if your hard disk driver software (also called formatting software) is out of date. Most hard disk vendors revised their formatting software for System 7. Alternatively, you may try a third-party driver utility like Silverlining or Drive 7. Apple's utility, HD SC Setup, works only with Apple hard disks. Version 7.0 of HD SC Setup comes with System 7.

If you have a question about a specific third-party hard disk or driver version, contact the vendor.

Pascal: Converting strings to numeric variables (1 of 2)

This article has been archived and is no longer updated by Apple.
Apple Pascal doesn't allow you to edit integer or real variable inputs. If the wrong data is entered by mistake, the program will be stuck with that data; worse yet, the system may crash.

The STRINGSTUF intrinsic unit is designed to avoid this problem. All data is entered in the form of strings, then converted to the appropriate data format by the unit. This allows you to edit the input data while it is still in string form. STRINGSTUF is located on the no-longer distributed Apple Graphics software package for the Apple II. If you're unable to locate a copy of this software, refer to the article that contains the STRINGSTUF code and instructions on its use: Apple Orchard, Vol. 1, #3, p. 59. The article is by Jo and Frank Kellner.

The STRINGSTUF unit and accompanying demo program are designed to run in versions of Pascal released later than version 1.0. Long integers are not supported in STRINGSTUF.

Locate STRINGSTUF in any unused segment number between 17 and 31. Install the unit in SYSTEM.LIBRARY, following the instructions in the Pascal Operating System Reference Manual on pp. 186-193.

System 7: A Multitasking Operating System

Article Change History

08/25/92 - REVIEWED
* For technical accuracy.

Is System 7 a multitasking operating system?

This article has been archived and is no longer updated by Apple.
Yes. Multitasking (previously known as MultiFinder) has been integrated into the system, so that System 7 is a multitasking operating system. With multitasking, people can work with several programs at the same time and even do some operations concurrently, like working while printing or copying files or recalculating a spreadsheet. With several programs running and available, people get more effective use from the computer.

In System 7, background printing and background copying of files are standard features. Consult your software developer for details on other multitasking capabilities.

At a more technical level, multitasking is the ability to do a number of tasks concurrently. System 7 uses a cooperative multitasking implementation to run several applications concurrently while doing tasks in the background.

System 7: When an Application from System 6 Won‘t Open

Why can't I open a document under System 7 that I opened under System 6?

This article has been archived and is no longer updated by Apple.
Because applications share available memory, your application may not have enough memory to open your document. You can easily increase the amount of memory that your application uses with System 7, so that you can open and work with any of your existing documents.

Here is a procedure to increase application memory:

1) Quit the application.

2) Find and select the application.

3) Choose Get Info from the File menu in the Finder.

4) At the bottom of the Info box is a field labeled "Application Memory Size." The number in this box is the amount of memory (like 1024K) used by the application when you run it.

5) To increase the memory for this application, change the number in the Application Memory Size field. For example, if you are running a Macintosh computer with 4MB of RAM, you might increase the number to as much as about 3000K. Consult your application's manual for specific recommendations.

Of course, you can always add more RAM memory to the computer.

System 7: "Not Enough Memory..." Message

When it's difficult to open applications or print, these tips will help you use Macintosh memory more efficiently. For more information about managing memory, see the "Macintosh User's Guide".
This article has been archived and is no longer updated by Apple.
To use System 7, your Macintosh needs at least 2MB of memory (4MB is recommended). If you customarily work with several programs at a time, you may wish to install more memory.

Use the Available Memory
If you get a message asking if you'd like to open a program using the available memory, click OK, and the program will open. This message appears when the available memory is greater than the minimum memory required to open the program, but less than the recommended amount. In rare cases, you may be unable to use some features of the program.

Quit Some Open Programs
When you open an application and see the "not enough memory" message, you should quit one or more open programs. Open the Application menu (right end of the menu bar) to see which programs are open. This message appears when the available memory is less than the minimum required to open the program.

Change a Program's Memory Size
You can often avoid memory problems by reducing or sometimes increasing a program's current memory size. In rare cases, reducing a program's memory size degrades performance.
Sometimes the "not enough memory" error is telling you that your system may have enough RAM available, but the application's "preferred memory size" is set too low. Check About This Macintosh in the Apple menu for the largest free block size to ensure that you have enough free space; increase the Preferred Size (Step 4 in the following table) to a larger amount (you may need to experiment).

Follow these steps to change a program's memory size:

1. Quit the program.
2. In the Finder, select the program's icon.
3. Choose Get Info from the File menu. The program's Info window appears.
4. Reset the memory size in the Preferred Size field.
5. Close the Info window
6. Try again to open the program.

Turn Off Background Printing
When background printing is on, you can print while using the computer for other work. If you don't need background printing, you can reduce the amount of memory required to print by turning it off.

Follow these steps to turn off background printing:

1. Choose the Chooser from the Apple menu.
2. In the Chooser window, select a LaserWriter icon.
3. Click the Background Printing: Off button.

Quit Some Programs Before Printing
When you print, you'll sometimes see the Application menu begin to blink. When this happens, follow these steps to quit a program and make more memory available for printing:

1. Choose Finder from the Application menu. You'll see an alert box.
2. Click OK to close the alert box.
3. From the Application menu, choose the program you want to close. The program becomes active.
4. Choose Quit from the File menu.
5. After quitting one or more programs, try printing again.

Set the Disk Cache to the Smallest Size
The disk cache is a portion of the computer's memory set aside to limit how often the computer must read from a disk. This speeds up the computer's performance. By reducing the size of the disk cache, you can make more memory available for application programs. Follow these steps to adjust the disk cache:

1. Choose Control Panels from the Apple menu.
2. Open the Memory control panel (double-click the Memory icon).
3. In the Memory control panel, click the down arrow repeatedly until the disk cache is the smallest possible size.
4. Choose Restart from the Special menu to restart the Macintosh.

Drag Optional Extensions Out of the Appropriate Folders
Extensions (also known as INITs) compete with application programs for memory. (System extension icons are often displayed in the bottom-left

portion of the screen when the computer starts up.) There are three types of extensions:

* Control Panels
* System Extensions
* Chooser Extensions

These extensions may be located in any of these folders:
* Control Panels folder
* System Folder
* Extensions folder

You can conserve memory by removing system extensions that you don't need. For instance, if your Macintosh is not connected to a host database, you can remove the DAL (Data Access Language) system extension. Likewise, if your Macintosh is not connected to a network, you can remove the AppleShare system extension. Follow these steps to remove system extensions:

1. Open the System Folder.
2. Open the appropriate folders
3. Drag the system extension icon out of the System Folder to another location on your hard disk.
4. Restart the computer.

Turn Off File Sharing
When file sharing is turned on, you can share information on your computer's hard disk with other users on a network. If you don't currently use file sharing, you can conserve memory by turning it off or removing it from the Extensions folder. Follow these steps to turn off file sharing:

1. Choose Control Panels from the Apple menu.
2. Open the Sharing Setup control panel (double-click the Sharing Setup icon).
3. Click Stop in the File Sharing section of the Sharing Setup control panel. A message appears asking how many minutes the computer should wait until file sharing is turned off.
4. Type a number and click OK.

Restart the Computer
If you have opened and closed a number of programs, your Macintosh memory can become fragmented so that you can't open a large program. When this happens, quit all the open programs, and restart the computer and then open the program.

System 7: Extensions Folder

What is the role of the Extensions folder?

This article has been archived and is no longer updated by Apple.
The Extensions folder inside the System 7.x System Folder contains "system extensions" (previously known as "INITs"), and miscellaneous software additions to your Macintosh computer, such as printer drivers and network drivers.

The Extensions folder is the first place that the System looks when loading system extensions at startup.

System 7.x implements a new capability for automatic installation for system resources. When you drag a system extension (INIT), control panel, font, or a desk accessory onto the icon of the System folder, the system automatically determines where the resource should go and places it there. If you drag a system extension (INIT) onto the icon of the System Folder, it gets placed in the Extensions folder.

Mac OS: Preferences Folder

What is the role of the Preferences folder?

This article has been archived and is no longer updated by Apple.

The Preferences Folder is a folder inside the System Folder. It provides a standard place for applications to store their special files, such as dictionaries, preference files, option files, settings files, resume files, and so forth. Application preferences can be reset to default values by throwing away its preference file; a new file will be created the next time the application is opened.

System 7: Sharing a Hard Disk with a System 6 Macintosh

Can I move a hard disk between a Macintosh computer running System 6 and a Macintosh computer running System 7?

This article has been archived and is no longer updated by Apple.

Yes. You can move hard drives between Macintosh computers running System 6 and System 7. When a hard disk is moved from System 6 to System 7, you will see a dialog box when you start stating that "This disk is being updated for new system software". This process does not affect any data on your disk. Rather, it means the system is creating a new System 7 Desktop file on the hard disk. Afterwards, you may use your hard disk as usual.

When a hard disk is moved from System 7 back to System 6, you will notice a few differences under System 6. First, you should rebuild the Desktop of the hard disk by holding down the Command and Option keys, while starting the Finder. If you don't do this, the first time you go back to System 6, some icons may not appear properly.

You may also notice two new folders which appear on your hard disk under System 6 which were not present under System 7. The first of these is the Desktop folder which will contain any items which you placed on the desktop under System 7. The second folder you will see under System 6 is the Trash folder. This folder will contain any items which were dragged to the Trash (but not emptied) under System 7.

Moving a disk between System 6 and System 7 is safe and will not damage any data.

Note: Locked media created under System 7 cannot be mounted under System 6 until they are unlocked.

Will my System 6 desk accessories work under System 7?

This article has been archived and is no longer updated by Apple.
Yes. Most all desk accessories (DAs) written for System 6 run under System 7. To use a System 6 desk accessory, you must first take it out of its "suitcase". Follow these steps:

1) Locate the desk accessory. It should appear in a file that has a suitcase icon. (Unless it was already part of the System 6 System file - in which case it would be in the System 7 System file.)

2) Open the suitcase icon by selecting it and choosing Open from the File menu, or by double-clicking on the suitcase. The suitcase will open into a window and show the desk accessory inside.

3) Drag the desk accessory out of the window and onto your hard drive. You can put the desk accessory anywhere on your hard drive. If you want to access the desk accessory from the Apple Menu, put the desk accessory in the Apple Menu Items folder.

Some desk accessories, like spell checkers and art effects, will need special installation procedures to work properly with System 7 (they may need to be installed in the System file, though Apple does not endorse or recommend this method). Check with the software developer for additional details on using these DAs with System 7.

Do Desk Accessories have to be in the Apple Menu Items folder?

This article has been archived and is no longer updated by Apple.
No. You may put and use your desk accessories anywhere on your hard disk (including the desktop or in the Apple Menu Items folder).

Putting a Desk Accessory into the Apple Menu

If you want to put a desk accessory into the Apple menu, drag the desk accessory onto the System Folder icon. Your desk accessory will automatically get placed in the Apple Menu Items folder.

Moving a Desk Accessory from The Apple Menu to the Desktop

If you want to remove a desk accessory from the Apple Menu and put it on the desktop instead, follow these steps:

1) Open your System folder.

2) Locate and open the Apple Menu Items folder.

3) Locate the desired desk accessory and drag it out of the Apple Menu Items folder and onto the desktop.

Using a Desk Accessory from System 6

You may find that older desk accessories appear in desk accessory suitcases. To use such a desk accessory, open the suitcase by double-clicking it. Then, drag the desk accessory out of the suitcase window. You can now use the desk accessory.

Apple Menu: Items Limit

Is there a limit to the number of items in the Apple menu?
This article has been archived and is no longer updated by Apple.
System 7.x and higher have a limit of 52 items that can be displayed in the Apple Menu Items folder.

The value of 52 was set for performance reasons. When more than 52 items are in the Apple Menu Items folder, available RAM for processing is limited (especially when the menu items have color icons), drastically slowing the display of menus. A decision was made to consider what "acceptable" performance was, and the value of 52 menu items was the threshold amount.

You can still place more than 52 items in the Apple Menu Items folder, but only the first 52 (alphabetically by name) are displayed. For more information on rearranging items in the Apple menu, see the following Tech Info Library article:

Article 8390: "**Mac OS: Changing Sequence of Apple Menu Items**"

Here are a couple of workarounds:

- Have folder aliases in the Apple Menu Items folder.
- Use the hierarchical menus in the System Software, or a third-party software that provides hierarchical menus. Hierarchical menus in System 7.5 and higher are controlled through the Apple Menu Options control panel.

System 7: INITs or System Extensions in System 7

Article Change History

09/25/92 - REVIEWED
* For technical accuracy.

How are INITs loaded in System 7?

This article has been archived and is no longer updated by Apple.
In System 7, INITs are referred to as "system extensions." The system looks for extensions in three places when loading them at boot time:

* First, it looks in the Extensions folder (located in the System Folder). This is the proper place to put your compatible INITs or system extensions.
* Second, it looks in the Control Panels folder (also inside the System Folder).
* Third, it loads any extensions it finds at the root level of the System Folder itself.

Published Date: Feb 18, 2012

System 7: How to Disable System Extensions

Can I disable system extensions (previously called INITs) under System 7?
This article has been archived and is no longer updated by Apple.
Yes. If your system crashes when you first turn it on, or if you are experiencing unexpected behavior with an application or in the Finder itself, you may have one or more system extensions (INITs) that are incompatible with System 7 or with each other.

If you suspect that problems you are experiencing with your system are due to extensions loaded in your System Folder, Extensions folder, or Control Panels folder, you can temporarily disable them by holding down the Shift key as you start your computer.

After you have started your Macintosh while holding down the Shift key, you can remove any extensions that may be causing problems. The next time you restart, all of your extensions will load as usual.

Holding down the Shift key when you start the computer turns off all extensions that may cause other things on your system not to work. You should do this only when you think a newly-added extension is the cause of your problems. Some system extensions are needed to do essential things like share files, access file servers, access CD-ROMs, and so on. However, you can continue to print even with the extensions disabled.

System 7: INIT Does Not Work in the Extensions Folder

Article Change History

08/20/92 - REVISED
* To make more clear; edited.

What should I do if an INIT does not work in the Extensions folder?

This article has been archived and is no longer updated by Apple.
INITs (called "system extensions" in System 7) that do not work when loaded to the Extensions folder should be moved to the root level of the System folder. Some INITs written for System 6 expect to be at the same folder level as the System file.

To put an INIT into the root level of the System folder without having it automatically routed to the Extensions folder, open the System Folder and drag the INIT into the folder's open window, rather than onto the icon of the System Folder. Automatic routing only occurs when you drop something onto the icon of the System folder.

If the INIT still doesn't work at the root level of the System Folder, check with the source to make sure the INIT is compatible with System 7.

Pascal: Intrinsic unit for Silentype procedures (1 of 3)

This article has been archived and is no longer updated by Apple.
Appendix D (pp. 53-59) of the Silentype reference manual indicates that all parameter procedures can be placed into an intrinsic library unit. This is a handy and valuable unit to have if you plan to use the Silentype printer in a Pascal program.

To extend the usefulness of the Silentype unit, two procedures have been added to this listing and another has been changed. These three procedures are discussed here; refer to the Silentype manual for a description of the remainder.

Procedure SetPage (Page: integer):

This procedure allows you to change from one high-resolution graphics screen to the other; however, only the first high-res page is used in the Pascal system.
Values: 1=first page; 2=second page.

Procedure ColdStart:

The ColdStart procedure resets the Silentype parameters to the default values as specified in the printer manual. This procedure is equivalent to turning off the power to the printer.
Values: none required.

Procedure WarmStart:

The Restore procedure as listed in the Silentype manual has been revised and renamed WarmStart. Included in the revision is the SetPage procedure. This procedure differs from ColdStart in that the parameters set by WarmStart are user-definable; that is, they reflect the particular setup that you find most appliable to your needs. For instance, you may set a darkness setting to 3 or 5, and so on.

Initialization Code:

The initialization code consists of a call to the ColdStart procedure. This call is executed when the unit is first brought into the system from the library to ensure that the printer is not retaining any settings from previous uses with either Pascal or BASIC. If you wish, you may change this code to WarmStart or another code of your choice; you may also leave the initialization section empty, though in that case you should still include the BEGIN and END.

Installing the Unit:

The Silentype unit comes ready for you to enter it, compile it and install it in your copy of SYSTEM.LIBRARY, though you may wish first to change the Intrinsic Code value or the contents of WarmStart to suit your individual needs. Refer to pp. 186-193 of the Apple Pascal Operating System Reference manual for the instructions for placing the compiled Silentype unit into your SYSTEM.LIBRARY.

* To add information about "cannot display all items" message.

How can I do a Find with multiple criteria?

This article has been archived and is no longer updated by Apple.
Do this through the "Find..." dialog in the Finder:

1) Click on the "More Options" button.

2) Select the first criterion you want to search and check "all at once".

3) Click the Find button.

4) After all the files meeting the first criterion are found and selected, choose "Find, More Options", enter the second criteria, and select "Search: the selected items".

5) Click the Find button.

Only those items that meet both criteria remain selected. You can repeat this procedure to narrow the search as much as you need.

If you get a message that not all items meeting the criteria could be displayed at once, the most likely reason is that some items are at the desktop level and could not be displayed in the window. Try moving those items from the desktop into the root level window of the volume. The other possible reason for the message is that you have run out of memory due to too large a search result. Try quitting any open applications to free up more memory.

System 7: How to Install FKEY Resources

How do I install FKEY resources to be used with System 7?
This article has been archived and is no longer updated by Apple.
As in System 6, FKEYs must be installed using a "resource moving" utility like ResEdit (version 2.0 or later).

Installing System 7 over a previous system does not remove FKEYs that were already installed in your system.

Note: The screen-capture FKEY (invoked by pressing Command-Shift-3) has been much improved in System 7. When you press Command-Shift-3, the system takes a "snapshot" of your screen and creates a TeachText file of the image. The resulting file contains an accurate image of your screen, even displaying colors and the image from multiple attached monitors.

Warning: The instructions in this article refer to using ResEdit. Apple Computer, Inc., is not liable for any damage done to your software through the use of ResEdit to alter software.

System 7: How to Rename File and Folder Icons

Article Change History

08/21/92 - UPDATED
* With additional tips on renaming.

How do I rename file and folder icons in System 7?

This article has been archived and is no longer updated by Apple.
In Finder 7.0, renaming icons is slightly different from System 6. To rename an icon you must click directly on the name of the icon and wait for the cursor to change to an I-beam. A box will appear around the name of the icon and you can then edit the name. The speed at which the box appears, making the file or folder name editable, is dependent on the double-click speed in the Mouse control panel.

But if you don't want to wait for the cursor to change to an I-beam, you can click once on the file or folder name and drag the cursor off the name. This will make the name immediately editable. Alternately, click anywhere on the icon and press Return to make the name immediately editable.

System 7: How to Customize an Icon

Can I customize an icon in System 7?
This article has been archived and is no longer updated by Apple.
Yes. Here's how to customize an icon in System 7:

1. Select the graphic you want to use for an icon. An icon in the Get Info window of any document or folder is a possible source.

2. Copy the graphic to the Clipboard by choosing Copy from the Edit menu.

3. In the Finder, select the icon you want to change.

4. Choose Get Info from the File menu.

5. Ensure that the Locked box in the lower-left corner of the Get Info window is not checked. You cannot customize the icon of a locked file.

6. Click the icon at the upper left of the Get Info window to select it.

7. Choose Paste from the Edit menu.

8. Click the close box to close the Get Info window.

You can change an icon back by clicking the icon in the upper-left corner of the Get Info window and choosing Cut or Clear from the Edit menu, or by using the Undo command (Command + Z).

Notes
- If the selected graphic is bigger than the icon in the Get Info window, it automatically shrinks to fit.
- Some icons cannot be customized, including those for locked items, control panels, and other parts of the system software.

Article Change History

* To give more details.

What happened to the "Set Startup" menu item that was in System 6?

This article has been archived and is no longer updated by Apple.
"Set Startup" under System 6 lets you switch between the Finder and MultiFinder and set certain applications and desk accessories to open automatically when you turn on your Macintosh.

System 7 has added more flexibility to this feature. Using System 7, you can have applications, documents, control panels, desk accessories, or aliases open automatically when you start you Macintosh.

To do this, just put the items you want opened into the Startup Items folder inside the System folder. If you want an application to open at startup but you don't want to move it from its current location, just make an alias of it and put that into the Startup Items folder.

System 7.x: PrintMonitor Documents Folder

What does the PrintMonitor Documents folder do?
This article has been archived and is no longer updated by Apple.
With System 7, you can print to a LaserWriter or a StyleWriter while you do other work with your Macintosh. For instance, you can print and continue working on a document at the same time. This is called "background printing."

When background printing is turned on for printers in the Chooser, files waiting to be printed are temporarily stored in the PrintMonitor Documents folder until the printer is ready to print them. This is all done in the background.

Direct-connect printers that use Grayshare, such as the Apple Color Printer, the StyleWriter II, the Personal LaserWriter 300, also use the PrintMonitor documents folder. The host computer handles the printer spooling, and temporarily stores files in the PrintMonitor Documents folder.

The ImageWriter does not support background printing.

The Views control panel in System 7 controls how the files and windows on your desktop are displayed.

You can change the font and font size the Finder uses to display icons, and how icons are arranged when you select Clean Up from the Special menu.

Another option is selecting how information is displayed in various list views (View by Name, Date, Kind, Size, Label). You can also change things like icon size, space available display, and what type of information should appear.

If you want to arrange your files in an icon view but in order of name, date, kind, size or label, first display the files by the view by which you want to sort (using the View menu. Then, change your view to one of the icon views, hold down the Option key, and choose Clean Up by... from the Special menu. Your last chosen view will be the parameter by which the icons are sorted.

System 7: Why Trash Icon Expands When a Floppy Is Mounted

Article Change History

Why does the trash icon expand when I insert a disk?

This article has been archived and is no longer updated by Apple.
In System 7, items dragged to the Trash are not deleted until you select Empty Trash from the Special menu. If you drag items from a floppy to the Trash, those items will appear in the Trash whenever that disk is inserted, until you empty the Trash.

If you insert a disk that has some items in the Trash, the Trash icon will bulge when you insert the disk to let you know this disk has items in the Trash.

System 7: The "Some items could not be opened" Message

Why do I get the message "Some items could not be opened" when I start my Macintosh?

This article has been archived and is no longer updated by Apple.
When a Macintosh starts, it looks inside the folder "Startup Items" inside the System folder and tries to open all of the icons it finds in that folder. This is useful when you have applications, documents, desk accessories, and control panels that you want to have opened automatically at startup.

If you see the message "Some items could not be opened" you have probably placed an icon that cannot be opened (like an INIT, system extension, printer driver, and so on) inside your Startup Items folder.

* To add more information.

What is the role of Sharing Setup?

This article has been archived and is no longer updated by Apple.
The Sharing Setup control panel lets you set up file sharing and network communication for your Macintosh. With this, you identify yourself and give yourself a password for authentication when you remotely access your Macintosh. You also name your Macintosh computer, so it can be identified when other users want to connect to your shared resources.

How to Turn on File Sharing

Follow these steps:

1) Open your Control Panel folder.

2) Open Sharing Setup Control Panel.

3) Type in your name, your password, and your computer's name.

4) Click the start button for File sharing.

5) Click the start button for Program Linking if you will be using that feature.

More information is contained in the Macintosh User's Guide.

What is the role of Users and Groups in System 7?

This article has been archived and is no longer updated by Apple.
The Users and Groups control panel lets you identify the names and passwords of users with whom you want to share specific folders or applications. With this, you can also set certain abilities regarding whether or not the user can connect to shared resources, or whether they change their connection password. User Setup also lets you create group icons and put multiple users into these groups.

How to Create a User

Follow these steps:

1) Open your Control Panels folder.

2) Open the Users & Groups control panel.

3) Select New User from the File menu.

4) Type the name of the new user and press the Return key.

The File Sharing Monitor Control Panel lets you monitor file sharing activity. It shows you the name of any connected users (actually the names you have allowed users to connect with) and the total time that the user has been connected in the current session.

This monitor also lets you disconnect any connected users. A thermometer-style meter indicates the amount of access by all connected users.

How to View File-Sharing Status

Follow these steps:

1) Open your Control Panels folder.

2) Open the File Sharing Monitor control panel.

How to Disconnect a File-Sharing User

Follow these steps:

1) Open the File Sharing Monitor control panel.

2) Click on (select) the user you want to disconnect from the Connected Users list.

3) Click Disconnect.

4) Type the number of minutes before the user is disconnected, and click OK.

How does file sharing differ from the AppleShare File Server?

This article has been archived and is no longer updated by Apple.
AppleShare File Servers are designed to perform much better than Macintosh computers using file sharing when large numbers of users with heavy load requirements are involved. Service from a Macintosh with AppleShare File server software performs approximately 25 percent better than a Macintosh using file sharing for the same configuration.

File sharing lets an individual directly share and control sharing of folders of information with a small group of individuals. An AppleShare file server provides centralized control of sharing by an Administrator for a large group of individuals. File sharing is built around the Macintosh user with the focus and emphasis on personal control of sharing local folders. The distinguishing marks of centralized file service includes issues regarding administration for large workgroups, performance, and central access. System 7's file sharing is a form of distributed file sharing.

Performance and access needs will determine which approach provides the best service. File sharing is best suited for small workgroup focus, with optimal performance for low sharing load situations. Centralized file servers like AppleShare are designed for high traffic with large numbers of users and are designed for continuous operation with no interruptions.

Using file sharing, up to 10 folders per machine can be shared, each having an unlimited number of enclosed folders. Up to 10 guest users can be connected to a networked hard disk, with up to 50 guest users identified in the Users and Groups file. This contrasts with 120 concurrent users for AppleShare 3.0.

If I am running System 7, can I share files, documents, or folders with a Macintosh running System 6?

This article has been archived and is no longer updated by Apple.
Yes. To set up your Macintosh computer to share files, documents, or folders, follow the instructions on setting up file sharing in the Macintosh User's Guide or search for other articles on the subject. You can share folders with any Macintosh (from the 512k enhanced and up), the Apple II, and any MS-DOS computer that uses AppleShare workstation software. Apple II and MS-DOS computers require special software and, in some cases, hardware.

About File Sharing in System 7 Through Mac OS 9

Personal File Sharing in System 7 through Mac OS 9 allows you to share files between two or more computers. This document describes setup and limitations.
This article has been archived and is no longer updated by Apple.

What does File Sharing do?

Personal File Sharing allows you share your disks or folders and the files they contain with other people on a network. Personal File Sharing is available to Macintosh computers using System 7 through Mac OS 9 that are connected to an AppleTalk or TCP/IP network. With your permission, others can view and even edit documents on your hard disk from their computer. You can control access to your information through passwords and setting access privileges (none, read, write, or read-write).

10 connected user limit

One way that Personal File Sharing differs from AppleShare IP server products and Mac OS X Server is that only ten users can be connected to the sharing computer at a given time. For more information, see technical document 45052: "**Mac OS 8 and 9: Personal File Sharing User Limits**"

Mac OS X File Sharing

This document describes File Sharing as implemented in System 7, Mac OS 8, and Mac OS 9. For information on Mac OS X, stop here and go to technical document 106461: "**Mac OS X: File Sharing**"

System 7 File Sharing

Create a network

Your computers must be physically connected on an Ethernet or AirPort network. For information on connecting two Macintosh computers together to share files, refer to article 106658: "**Macintosh: How to Create a Small Ethernet Network**"

How to Turn on File Sharing

1. Choose Control Panels from the Apple menu and double-click the Sharing Setup control panel.
2. Make sure that you have identified your computer to the network. You have to give an Owner Name, an Owner Password, and a Macintosh Name.
3. Click the Start button. Its label changes to Cancel and the status line describes what is happening while file sharing is starting up. It may take a minute or so to complete. When the status line says file sharing is on and the button is labeled Stop, your computer is ready to share files. If you start file sharing when AppleTalk is not active, it will be automatically turned on for you.
4. Close the Sharing Setup control panel and the Control Panels folder.

How to Share a Folder
Follow these steps:

1. Select the folder.
2. Choose Sharing from the File menu.
3. Click Share This Item And Its Contents.
4. Close the Privileges Window.
5. When asked for confirmation, click Save.

How to Log on as Owner
As the owner or administrator of two Macintosh systems - a desktop and a portable model for example - file sharing can be even easier. An AppleTalk network can be as small as two Macintosh computers connected together with LocalTalk (or compatible) cabling. Once connected together, either Macintosh computer can turn on file sharing. There is no need to share folders, because the owner can access everything. From the other Macintosh, you can connect with the AppleShare workstation software as the owner. Follow these steps to connect remotely as the owner:

1. Open the Chooser.
2. Select AppleShare.
3. Select your Macintosh computer.

4. Type your name, as you typed it in Owner Name field in the Sharing Setup dialog on the Macintosh you are connecting to.
5. Type your password, as you typed it in Owner Password field in the Sharing Setup dialog on the Macintosh you are connecting to. You will see all the disk resources connected to the remote Macintosh as if you are looking directly at its desktop. Make an alias of the volume for even easier future access.

Pascal II: Operand Formats (1 of 2)

When you need to send data (especially complex data formats, such as strings) to an assembly routine from a Pascal host program, it can be very useful to be familiar with the internal structure of Pascal variables. This 2 part article describes a few of the more commonly used variable types; for a complete description of the more complex variables, including records and arrays, see pp. 227-228 of the Apple Pascal Operating System Reference Manual.
This article has been archived and is no longer updated by Apple.
Machine language (assembly) routines are commonly used either when (a) speed is critical, or (b) when the code must access other assembly routines (such as PROMs or I/O drivers) that can't be reassembled as part of the program. Also, bit manipulations such as right-shift are much easier to do in assembly than in Pascal.

In the UCSD Pascal system, it's fairly easy to create short assembly programs which can be linked into a Pascal host program. In some cases, it may be sufficient to merely call the assembly routine; most routines require that data be passed to them, though. Data is passed to or from routines by means of a "parameter", a temporary variable created by Pascal specifically for that purpose. The term "Var parameter" implies that the address of the actual variable is passed to the routine as a parameter instead of its value.

Certain types of variables may be passed by value, but any variable may be passed by name by simply declaring it to be a Var parameter. Pascal does not allow parameters of variable length (with the exception of certain sets and long integers) to be passed on the CPU stack, since doing so could end up filling the stack to capacity and thereby crashing the operating system. These parameters, therefore, are automatically used as if defined as Var parameters. A good explanation of the various methods of passing parameters may be found in Peter Grogono's book, "Programming in Pascal".

Before delving into the details, let's define some terms and conventions which we'll use later on:

Bit = a binary digit (0 or 1). A bit is the smallest unit of information which can be stored in a computer.
Nybble = 4 bits (half a byte). A hexadecimal digit is one nybble (pronounced "nibble").
Byte = 8 bits (2 nybbles). This is the unit of storage which the 6502 processor uses.
Word = 2 bytes (16 bits). A word is the unit of information which Pascal uses.
LSB = least significant bit
MSB = most significant bit

```
decimal 65535 <--------memory---------> 0
hexadecimal $FFFF <--------memory---------> $0000 addresses
MSB LSB
```

This diagram of memory structure is useful for understanding the format of variables: although we're used to writing numbers from left to right, Pascal reads data from memory FROM RIGHT TO LEFT, starting at the least significant byte.

Integers:
Integers in UCSD Pascal are whole numbers between -32768 to +32767, inclusive. They are stored in one word (2 bytes). Negative integers are represented in "two's complement," which means that they appear to have positive values greater than 32767; the negative integer is arrived at by subtracting 2 ^ 16 (65536) from this positve value. Similarly, large positive integers are stored as a complementary negative numbers (cf. Integer BASIC). The sign bit (MSB) is 0 if positive, 1 if negative.

```
<----byte----> <---byte--->
15 14 . . . . . 8 7 . . . . . 0 <== 16 bits
Sign Integer Value
```

Example: the number 3 is represented in binary as:

MSB 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 LSB

However, -3 is represented as:

MSB 1 1 1 1 1 1 1 1 1 1 1 1 1 1 0 1 LSB

which also reads as 65533 (or 65536-3)!

Integers may be passed by value or as Var parameters.

Reals:
Real numbers, in UCSD Pascal, are floating point numbers between +/-1.17550E-38 to +/-3.40282E+38, inclusive. Real numbers take up four bytes (2 words) of storage. Their binary representations are similar to the proposed IEEE standard for floating point numbers:

```
31 30 . . . . . 23 22 . . . . . 0 <== 32 bits
Sign Exponent Mantissa
```

"Mantissa" is the name given to the decimal portion of a number; by convention, it's expressed in scientific (exponential) notation. The "exponent" indicates the power to which the mantissa is raised. The exponent is represented in base 2 (2^n). The number 3 x 10^2, for instance, is defined as having a mantissa of 3, an exponent of 2, in base 10 (decimal).

The sign bit refers to the sign of the mantissa; it's 0 if positive, 1 if negative. The exponent is "offset" by 127; that is, a value of 127 in the exponent field corresponds to an exponent of 0. Similarly, if the value is 1, the exponent is -126, and if the field is 254, the exponent is +127. A value of 0 indicates that the real number is 0.

The mantissa of the real number is stored in normalized format in bits 0-22. "Normalizing" a number means adjusting it so that the highest bit is significant (that is, set to 1). The exponent indicates how many times (and in which direction) the value was shifted during normalization.

Notice that the MSB of the mantissa of any non-zero number that has been normalized is always a one. Zero can be treated as a special case: the exponent is simply set to zero. So, to gain additional precision, the mantissa has an implied "1" that is not stored, resulting in a functional 24-bit mantissa, even though only 23 bits are actually used. This gives slightly more than a 6-decimal-place (single precision) accuracy.

To make this clearer, let's look at some examples:

Real number = 1

MSB 0 01111111 00000000000000000000000 LSB
Exponent = 127 (2^0) Mantissa = 1 (the implied 1 isn't stored)

Real number = -9.9
MSB 1 10000010 00111100110011001100110 LSB
Exponent = 130 (2^3) Mantissa = 99000015

In the second example, the real number (in binary) appears as 1001.1110011...

During normalization, the decimal point is moved to the left 3 times (incrementing the exponent), and the most significant bit becomes implied. The sign bit is 1, indicating that the number is negative.

Real numbers may be passed by value, or else they may be defined as Var parameters and then passed by address.

Can file sharing be disabled?

This article has been archived and is no longer updated by Apple.
Yes. File sharing can be disabled in two ways:

* By not enabling the sharing functionality with the Sharing Setup control panel (the button next to File Sharing should say "Start").

* By not installing the file sharing software. Either choose the Custom option in the system software Installer program, or simply drag the File Sharing extension out of the Extensions folder in the System Folder.

Here are the steps for turning off File sharing:

1) Open your Control Panel folder.

2) Open Sharing Setup Control Panel.

3) Click the "Stop" button for file sharing. The button name should change to "Start".

Yes. You can share applications in two ways:

* by sharing the folder that contains the application, so that multiple users can access it; and

* by sharing the program directly for access by remote program linking.

If you share the program by sharing the folder that it is in, then you must be aware of two issues:

* Some applications are not multi-user or AppleShare-aware and so cannot be used by more than one person at a time.

* You must adhere to the software license agreement provided with the application. Most applications only allow one user per copy.

MS-DOS-based computers can access folders and files shared by Macintosh computers by using the AppleShare PC software available from Farallon Computing. This software provides the same capabilities that Macintosh computers have when connecting to shared folders with the AppleShare workstation software.

The Farallon product is PhoneNET Talk software, formerly AppleShare PC. With it, any MS-DOS or Windows personal computer can share networked printers, file servers that support AppleTalk Filing Protocol (AFP), and AppleTalk network applications over an AppleTalk network.

Support for multi-user access to a document depends on the application. All the major Macintosh database programs support multiple-user access to a shared data file and many other Macintosh programs are AppleShare-aware to the point that they also support multi-user access to a single document. Some applications, like Microsoft Word, let a user open a shared document as "read-only." This means that other users can also open the same document as read-only.

Yes. Users can connect to shared information through a variety of means. Using the AppleShare workstation software yields the most consistent results. File sharing, Novell, 3Com, and other vendors support the AppleShare workstation software. Other vendors that don't support the AppleShare workstation software can coexist with AppleShare solutions.

However, once shared, folders accessed with the AppleShare workstation software cannot be "re-shared" with Macintosh File sharing. Macintosh File sharing only lets you share locally connected folders.

Pascal II: Operand Formats (2 of 2)

When you need to send data (especially complex data formats, such as strings) to an assembly routine from a Pascal host program, it can be very useful to be familiar with the internal structure of Pascal variables. This 2 part article describes a few of the more commonly used variable types; for a complete description of the more complex variables, including records and arrays, see pp. 227-228 of the Apple Pascal Operating System Reference Manual.

This article has been archived and is no longer updated by Apple.

Characters:

Characters, by ASCII definition, are simply integers between 0 to 255, inclusive. Characters take up one word of storage. The ASCII value of the character is stored in the least significant byte. The most significant byte is not used by Pascal and should be ignored.

```
15 . . . . . 8 7 . . . . . 0 <== 16 bits
unused ASCII
```

Example: the character "A" has an ASCII value of 65 (hexadecimal 41). The binary representation is:

```
MSB x x x x x x x x 0 1 0 0 0 0 0 1 LSB
<---- not used----> 4 (hex) 1
```

Characters can be passed either as actual parameters (by value) or as Var parameters (by address).

Strings:

A string is a packed array of characters that can be from one to 256 bytes long. The first byte of a string always contains a number from 0 to 255; this number indicates the length of the string. One character is stored per byte, and the string ends on a word boundary--that is, if the last character in the string is the first byte of a new word, the other byte of the word is also reserved and not used by the string.

Each character of the string can be accessed in a packed array of characters; you cannot, however, access the length byte (the 0th element). Doing so causes the message "Value Range Error" to be displayed.

Example: The string "ABCD" has a length of 4. It looks like this:

```
S[4] S[3] S[2] S[1] S[0]
MSB 01000100 01000011 01000010 01000001 00000100 LSB
"D" "C" "B" "A" 4
```

Pascal always passes strings by address, since strings' lengths may vary.

Pointers:

Address pointers are unsigned integers that occupy 1 word of storage. Their format is identical to that of integers, except that their values may range from 0 to 65535. The value of a pointer, in this implementation of Pascal, is the memory address of the object being described.

Example: The address of AN0 (one of the annunciator ports) is hex C058 (49240 decimal). This address is stored as:

```
MSB 1 1 0 0 0 0 0 0 0 1 0 1 1 0 0 0 LSB
<--------> <--------> <--------> <-------->
C 0 5 8
```

Pointers, like integers, may be passed by value or by reference (as a Var parameter).

Long Integers:

Long integers are a special type of variable, first defined at UCSD as part of their extensions to the Pascal language. They are primarily used to handle calculations involving numbers which (a) cannot be represented accurately in floating point (real) format, and (b) are too large to store in integer format.

Long integers are stored in BCD (binary coded decimal)--one digit per nybble. One entire word is reserved for the sign of the long integer, and the variable must end on a word boundary. Four digits can be contained in one word, so the smallest definable long integer takes up two words of memory. The numbers are padded with leading zeroes when necessary to fill up the last word. The sign is 0 if positive and 255 if negative. (One byte is used for the sign.)

To illustrate the structure of long integers, let's take a specific example: the long integer -123456 takes 3 words: one for the sign, and two for the digits (since they are stored in multiples of 4). This long integer is stored in the following format:

```
<---- each digit is one nybble --->
MSB 6 5 4 3 2 1 0 0 0 0 F F LSB
<- word -> <- word -> < sign word >
```

A long integer should always be passed by address, since its length depends on its definition.

Booleans:
The Boolean (binary) variable can have two values: TRUE and FALSE. Booleans are most commonly used in determining yes/no conditions, such as equality or set inclusion. Boolean variables are stored in one word, though only the LSB (least significant bit) is used. TRUE is represented by a 1; FALSE is represented by a 0.

```
MSB 15 . . . . . 8 7 . . . . . 0 LSB
Boolean
```

UCSD Pascal does not allow direct printing of Boolean variables. For example:

```
Program PrintBoolean;
Var A: boolean;
Begin
A := FALSE;
Writeln (A); (* this is illegal *)
If A = FALSE Then Writeln ('FALSE') Else Writeln ('TRUE'); (* this is correct *)
End.
```

Booleans are most efficient in packed arrays, where each bit of the word is utilized. DrawBlock is probably the best-known example of this use. An excellent example of the use of boolean packed arrays is in the GrafDemo program on the Apple Pacal diskette APPLE3.

Boolean variables may be passed by value or by address.

Other Types:
In addition to all the above standard types, Pascal allows the programmer to define a wide variety of non-standard variable types. Probably the most popular example of this is the SET.

A set is an arbitrary collection of elements with each element assigned an ordinal position (that is, represented by a number). Each element of the set is represented by a name; you may choose any word for this name, except for (a) words reserved by Pascal, and (b) other variable definitions already in use. Each name is then associated with one bit in the data definition, beginning with bit 0. The set is stored in memory as a series of bits identified by the ordinal position of the element in the type definition. A set must end on a word boundary: for example, 17 elements would take up 2 words, even though only one bit of the second word is actually used.

Example:
Type Colors = (Red,Green,Blue,Yellow,Black,White);
ColorSet = Set of Colors;

is a set of colors. Red occupies position 0, and white has position 5.

```
<----------one word----------->
MSB 0 0 0 0 0 0 0 0 0 0 1 1 1 1 1 1 LSB
W B Y B G R
h l e l r e
i a l u e d
t c l e e
e k o n
w
```

Sets may be passed either by address or by value, with certain restrictions. See p. 203 of the Pascal reference manual for details.

In general, complex record types consist of one or more standard types, each stored as described above. For the last word on Pascal data types, read Niklaus Wirth's Report in "User Manual and Report" by Jensen and Wirth.

Can I change my file sharing password from a remote location?

This article has been archived and is no longer updated by Apple.
Yes. You can connect to one Macintosh from another Macintosh on the same AppleTalk network and change your password with the Set Password button, provided that file sharing is enabled on your Macintosh. You must be using AppleShare workstation software 2.0 or greater (included any System 6 versions) to access your System 7 Macintosh.

Follow these steps to change your password remotely:

1) Open the Chooser.

2) Select your Macintosh with the AppleShare workstation software.

3) Click the Set Password button.

4) Type your new password.

5) Press Tab and type the current password.

6) Click OK.

7) Type your new password to reconfirm your change.

6) Click OK.

Will File sharing slow down my Macintosh when someone logs onto it?

This article has been archived and is no longer updated by Apple.
File sharing operates during the idle cycles on a user's machine. How often it uses those idle cycles or makes a higher-level request for more cycles depends on how heavy the requests are from the remote users connected to your Macintosh computer. During heavy access requests for files from remote users, the Macintosh manifests mouse jumping and varying degrees of slowness.

What are outline fonts?

This article has been archived and is no longer updated by Apple.
Outline fonts consist of mathematical descriptions of each character. Each character is defined by a series of lines and curves, and can be scaled to any size. Examples of outline fonts are PostScript and TrueType. You can find PostScript outline fonts in several of Apple's LaserWriter printers. Outline fonts give smooth, sharp text at any size when printed and (with TrueType) on the screen.

What is the Edition Manager?

This article has been archived and is no longer updated by Apple.
The Edition Manager is a new feature in System 7 that provides the ability to automatically update documents. New Edit menu commands let users "Publish" data as "editions" to other documents, and "Subscribe" to editions that remain linked to the original source document. When the published data (the edition) is edited, the changes are copied automatically to all its subscribers, on the same machine or across the network.

Applications must be updated to take advantage of the Edition Manager. Contact each application's publisher for details.

How does Publish and Subscribe work?

This article has been archived and is no longer updated by Apple.
Publish and Subscribe work only with applications that have been revised to take advantage of this feature in System 7.

To use Publish and Subscribe, follow these steps:

1) Select some data you want to place in another application or document as a "live" copy.

2) From the Edit menu, select "Create Publisher". This brings up a dialog box asking you to name the Edition file that will connect the Publisher to the other documents subscribing to this data.

3) After you have created the Edition file, go to the document or application where you want to use this data and select "Subscribe To..." from the Edit menu.

This places a live copy of the data in your document. From this point on, whenever you modify the original publisher data, the Subscriber is automatically updated, too.

System 7: Why Upgrade

* For technical accuracy.

Why should I upgrade to System 7?

This article has been archived and is no longer updated by Apple.
Apple recommends that all Macintosh users upgrade to System 7. Finder 7.0 offers powerful new capabilities and greater ease of use. Its features include:

* Fast access to your information. System 7 offers a fast file-find, so you can locate your files quickly and easily. You can also access your most frequently-used files, applications, and folders from the Apple Menu.

* More flexible ways to view files. For example, by selecting the Outline view, you can see several folders in one window simultaneously. Another facility called "aliases" helps you organize your hard disk the way you want.

* Virtual Memory with System 7. Without adding more RAM, you can have more memory to run more applications through virtual memory and 32-bit addressing. With virtual memory, the computer uses part of the hard disk to increase the amount of physical memory. For example, a 4MB Macintosh computer appears to have 8MB. With this additional memory, you can run more applications. 32-bit addressing makes it possible to access more than 8MB of memory in their system.

* Share files on your Macintosh with others. You can share your files with other people on the same network without dedicating a computer to act as a file server.

* The ability to access information regardless of where it's located.

* Multitasking. You can run several applications simultaneously for greater productivity. For example, you can work on a memo while printing a spreadsheet.

* Improved window handling.

* Improved text with TrueType fonts. You will see sharper-looking text on both your screen and your printer.

* A color interface for Macintoshes supporting color.

* A complete on-line Help system using System 7's new Balloon Help.

All of the things mentioned above work without you having to buy a new application. System 7 maintains and enhances your investment in your computer and your applications. In addition, software developers are working on many new and powerful applications that take full advantage of System 7 features.

See the "What's New in System 7" guide for more details.

* To provide additional information.

How do I install System 7?

This article has been archived and is no longer updated by Apple.
System 7 ships with an application named "Installer" that installs System 7 onto your Macintosh computer. You can run Installer from a set of floppy disks or from a file server.

IMPORTANT: You cannot "drag-install" System 7. You must use the System 7 Installer to install system software.

Installing from Floppy Disks

To upgrade your Macintosh to System 7 using floppy disks, follow these steps:

1) Shut down your Macintosh computer.

2) Insert System 7's "Install 1" disk into your Macintosh computer.

3) Turn on your Macintosh computer and push in the "Install 1" disk.

4) After reading the "Welcome to the Installer" notice, click OK.

5) If you have more than one hard disk, use the "Switch Disk" button to select the hard disk of your choice.

6) Click the Easy Install button.

7) The Installer will instruct you to insert the remaining System 7 floppy disks.

Installing from a File Server

To upgrade your Macintosh computer to System 7 using an AppleShare File Server, follow these steps:

1) Connect to an AppleShare File Server containing System 7.

2) Double-click on the Installer application in the "Install 1" folder.

3) After reading the "Welcome to the Installer" notice, click OK.

4) If you have more than one hard disk, use the "Switch Disk" button to select the hard disk of your choice.

5) Click the Easy Install button.

By using the Easy Install button, the Installer will automatically update your Macintosh computer to System 7. Easy Install also checks to see what printer drivers and EtherTalk/TokenTalk drivers are present in your System folder. If it locates a printer driver and/or network driver that should be updated, it will do so automatically.

For more information about installing System 7, especially if you are

having a difficult time or are experiencing compatibility problems, search for "System 7" and "Clean Install".

Pascal: Run-time errors

This article has been archived and is no longer updated by Apple.
Run-time errors generate an error message, as well as a set of numbers that refer to the instruction during which the error occurred. "S" stands for "Segment", "P" for "Procedure" and "I" for "Instruction Count". These can be correlated with the textfile by using the System List options, (*$L+*) or (*$L<filename>*), while compiling. Doing so produces an annotated listing of the text, with the S, P and I numbers included.

For example, here's a very simple program compiled with the listing option:

```
(1) (2) (3:4) (5)<--Text---------->
1 1 1:D 1 (*$LPrinter:*)
2 1 1:D 1 Program Example;
3 1 1:D 3
4 1 1:D 3 Var S:string;
5 1 1:D 44
6 1 1:0 0 Begin
7 1 1:1 0 Readln(S);
8 1 1:1 21 Writeln(S)
9 1 1:0 40 End.
```

Key:

(1) Line number of text

(2) Segment number (S#): When S# values do not appear in your listing, the error occurred in that segment of the operating system. S#0 is System.Pascal, while S#17-31 are usually SYSTEM.LIBRARY segments.

(3) Procedure number (P#) is the number within the segment designated by the S#.

(4) Nesting level (D=declaration)

(5) Instruction count (I#) is the number of instructions counted from the beginning of the procedure. It indicates the count at the beginning of each line; a value between two lines, then, means the error occurred in the middle of the line.

Warning: When using Apple Pascal Version 1.0, do not use $L+ as your listing option. Doing so will cause you to lose your code file, and possibly your operating system. Instead, specify a disk file on a volume other than the one that you wish to be the destination of your code file. Better yet, use (*$LPrinter:*) to put the listing directly onto your printer. The $L+ option works correctly in later versions.

System 7: How to Upgrade over a Network

Can I upgrade my Macintosh computer to System 7 over a network?

This article has been archived and is no longer updated by Apple.
Yes. You can upgrade your Macintosh computer over an AppleTalk network. Your network administrator needs to have loaded the System 7 installation software onto a file server and made that software available to you. To upgrade your Macintosh computer to System 7, run the Installer from the server. It is not possible to upgrade all Macintosh computers remotely on a network from one central Macintosh computer.

Requirements

To upgrade your Macintosh computer over the network, you must have the AppleShare Workstation Client software installed on your machine. The Client software is a standard part of System 6.0.7. You can tell whether the Client software is installed on your machine by opening the Chooser and confirming that the AppleShare icon is available in the upper-left panel of the Chooser window. Check with your network administrator for additional details.

Procedure

Follow these steps:

1) Ask your network administrator the name of the file server and volume where the installation software is located.

2) Use the Chooser desk accessory to connect to the file server/volume in step 1.

3) On the server volume, locate the folder containing the Installer program.

4) Open the Installer program.

5) In the Installer program, choose your hard disk and click Install.

How is publish and subscribe different from Copy and Paste?

This article has been archived and is no longer updated by Apple.
Copy and Paste are useful when you want to move data between documents and applications and you want separate copies (versions) of the data in each place. Publish and subscribe maintains a connection, so that the "subscribers" always reflect the current data in the "publisher."

For example, if you want a fixed version of a document, like a "Report-Draft 3," then you could copy and paste into your document. However, if you want your document to always reflect the most recent version of "Report," then you would choose publish and subscribe.

File sharing shares entire folders (and their contents) and hard disks between users on the network. Assuming you have been given permission, you can view and edit documents just as if they were stored on your local hard drive.

Publish and subscribe lets users share sections of documents between themselves by placing the connecting edition file on a file server.

Yes. When an edition is created, the publisher can save the edition file on a shared file server (including your own disk if it is shared using System 7 file sharing). Other users on the network can access the edition file on the file server and subscribe to it.

For instance, Pierre needs to create a presentation using some numbers in a spreadsheet that Marie has prepared on her system. Marie can publish the numbers from her spreadsheet and save the resulting edition file to a server that she and Pierre both share. Pascal: Real number format

This article has been archived and is no longer updated by Apple.
Real numbers in UCSD Pascal are floating point numbers between +/-1.17550E-38 and +/-3.40282E+38, inclusive. Real numbers take up four bytes (2 words) of storage. Their binary representation is similar to the proposed IEEE standard for floating point numbers:

31 30 . . . . . 23 22 . . . . . 0 <== 32 bits
Sign Exponent Mantissa

"Mantissa" is the name given to the decimal portion of a number; by convention, it's expressed in scientific (exponential) notation. The "exponent" indicates the power to which the mantissa is raised; it's represented in base 2 (2^N). The number 3 x 10^2, for example, is defined as having a mantissa of 3 and an exponent of 2, in base 10 (decimal).

The sign bit refers to the sign of the mantissa; it's 0 if positive, 1 if negative. The exponent is "offset" by 127--that is, a value of 127 in the exponent field corresponds to an exponent of 0. Similarly, if the value is 1, the exponent is -126, and if the field is 254, the exponent is +127. A value of 0 indicates that the real number is 0.

The mantissa of the real number is stored in normalized format in bits 0-22. "Normalizing" a number means adjusting it so that the highest bit is significant (that is, set to 1). The exponent indicates how many times, and in which direction, the value was shifted during normalization.

Notice that the MSB of the mantissa of any non-zero number that has been normalized is always a one. Zero can be treated as a special case--the exponent is simply set to zero. For the sake of additional precision, then, the mantissa has an implied "1" that is not stored, resulting in a functional 24-bit mantissa, even though only 23 bits are actually used. This structure yields slightly more than a 6-decimal-place (single precision) accuracy.

Real numbers may be formatted for output by means of field-width designations. As described on pp. 36-37 of the Apple Pascal language Reference Manual, the output specification has the following form:

Real : FieldWidth : FractionLength

where FieldWidth is the minimum number of characters written, including the decimal point (default=1). FractionLength is the number of digits to be written after the decimal place (default=5). Thus, a field specification of R:8:3 indicates the real variable R, printed within a field size of 8, with 3 of those digits appearing to the right of the decimal. A FractionLength of zero is illegal.

If the field size necessary for displaying the variable accurately is greater than the formatting specification, the formatting is ignored. If the size is smaller than FieldWidth, the field is padded with blanks to the left of the variable; the variable is thereby right-justified.

What is InterApplication Communication (IAC)?

This article has been archived and is no longer updated by Apple. InterApplication Communication describes the way applications use new features of System 7--the Edition Manager and AppleEvents--to cooperate more closely and improve the users' work flow.

Applications that implement the Edition Manager provide the ability to automatically update documents. New Edit menu commands let users "Publish" data to other documents and "Subscribe" to data that remains linked to the original source document. When the published data is edited, the changes are copied automatically to all its subscribers on the same machine or across the network. For example, the user can subscribe to a spreadsheet table in a word processing document. When the spreadsheet changes, the word processing document gets the change automatically.

Apple events make possible even more complex interaction between applications. It provides an invisible messaging language that will let programs share data and commands. The user sees Apple event-aware applications as those that can request services from each other. For example, an accounting package can pass inventory data to a spreadsheet and retrieve a graph of that data for display in its own report.

What is AppleEvents? Is the implementation of AppleEvents the same for all applications?

This article has been archived and is no longer updated by Apple.
AppleEvents is the underlying messaging language that applications use for complex communication with other applications. For the user, Apple event-aware applications are applications that can use services of other applications, either on the same machine or across the network. These applications use Apple-event messages as intelligent hooks to share functionality with other applications. AppleEvent implementation is application-specific, in that different types of programs will implement different sets of AppleEvents (for example, databases will use different sets of AppleEvents than word processors). All implementations will support a set of core events, which are defined by Apple.

Here are several examples:

* An accounting package can pass inventory data to a spreadsheet and retrieve a graph of that data for display in its own report.

* Utility packages like spell checkers, thesauruses, or formula editors can work generically with Apple event-aware applications.

* An application can request that a more sophisticated program display a specialized graphics format like TIFF in the requesting application window.

Applications vary in terms of how they implement AppleEvents. Check with your specific software manual for details about how to use this feature with your chosen software.

What is virtual memory?

This article has been archived and is no longer updated by Apple.
Virtual memory (VM) extends the user's available, physical random access memory by treating the hard disk - transparently to the user, with the exception of a slight loss of speed - as if it were additional RAM. With virtual memory you can run more applications at once and work with larger amounts of data than you can without virtual memory.

System 7: Macintosh Computers That Can Use Virtual Memory

Which Macintosh computers can use virtual memory?
This article has been archived and is no longer updated by Apple.
Any Macintosh computer which uses the 68030,68040, or PowerPC microprocessor can use virtual memory. A Macintosh computer with the 68020 microprocessor is virtual memory capable with the addition of a 68851 PMMU coprocessor.

A current listing of Macintosh computers which support virtual memory follows:

Compact Macintosh:

Macintosh SE/30
Macintosh Classic II
Macintosh Color Classic

Macintosh Performa:

System 7: Maximum Virtual Memory

What is the maximum amount of virtual memory I can use under System 7?
This article has been archived and is no longer updated by Apple.
The maximum amount of virtual memory available depends on the Macintosh model. The Macintosh II, IIx, IIcx, IIci, IIsi, and IIfx models can address a maximum of 13MB of virtual memory. The maximum of 13MB assumes that the user has only a NuBus video card installed. Each additional NuBus card installed in your Macintosh will decrease your maximum amount of virtual memory by 1MB.

The Macintosh SE/30 can address a maximum of 13MB of virtual memory.

Additionally, the Macintosh IIci, IIsi, and IIfx models can operate in 32-bit addressing mode. When operated in 32-bit addressing mode, these Macintosh models can address a maximum of 1GB (one gigabyte, or 1,024MB) of virtual memory.

Note: the maximum amount of virtual memory available on your Macintosh computer is also limited by available space on your hard disk.

System 7: How to Turn Virtual Memory On and Off

How can I turn virtual memory on and off?

This article has been archived and is no longer updated by Apple.
Virtual memory is controlled with the Memory Control Panel. Note: After turning virtual memory "ON", you need to restart your Macintosh computer to activate it.

System 7: Disk Space Needed for Virtual Memory

How much disk space do I need to use Virtual Memory?

This article has been archived and is no longer updated by Apple.
While virtual memory (VM) is running, you may notice that a portion of your hard disk is allocated to VM. The amount of space used for virtual memory depends the amount of virtual memory you request.

For example:

Physical Memory available in Mac setting	Virtual Memory used by VM	Disk Space used by VM
4MB	8MB	8MB
8MB	13MB	13MB

System 7: 32-Bit Addressing

1. What is 32-bit addressing?
2. How does it work?
3. Why do I get Type 1 errors?

This article has been archived and is no longer updated by Apple.

1. What is 32-bit addressing?

32-bit addressing means that you can install and access more than 8MB of physical RAM in your Macintosh. This means you can work with very large data files, very large applications, or many applications concurrently. 32-bit addressing is most attractive to Macintosh users working with large memory-intensive problems. While virtually anyone can benefit from the large amount of memory offered by 32-bit addressing, it will immediately benefit database users, color-graphic users, CAD/CAM users, and programmers. While 32-bit addressing may seem to benefit a small percentage of Macintosh users today, users can expect to soon see powerful "general purpose" tools benefit from 32-bit addressing.

More technically speaking, 32-bit addressing lets most recent Macintosh models access the entire 1GB memory range of the 68030 microprocessor. The basic software and hardware of the Macintosh already support the 32-bit addressing model, but any Macintosh using System 6 is limited to using only 8MB of memory because 32-bit addressing was not yet fully implemented.

In System 7, 32-bit addressing is fully implemented allowing most Macintosh computers access to greater than 8MB of memory. This expanded memory is important for high-end users working with many applications, complex graphics documents, large databases, and so on.

The term "addressing" refers to the number of binary digits (bits) that make up each memory address. Addressing directly determines the maximum amount of memory possibly available.

2. How does it work?

Binary numbers

To understand what happens with addressing, it is first necessary to understand what address bits are. The number system we're most accustomed to is the decimal system, otherwise known as the Base 10 system. In this system, all the numbers are relative to ten digits (0-9). When a number value exceeds the tenth digit, we add one to the value in the next column and and start over in the first column. Hence, when 1 is added to the number 09 we get 10. When we add 1 to 099, we get 100, so forth and so on.

Base 10 relies on there being exactly ten unique values per digit. Base 10 is not the only number system around. In the early days of computers, it was realized that it is much simpler to build data storage device such as a vacuum tube or a transistor with two possible value states(0 or 1) than it was to build one with 10 possible values(0 through 9). Therefore, someone came up with the idea of defining information in Base 2 format.

With the Base 2 number system, instead of counting your digits 0,1,2, ╔,9 and then adding a one to the next column, you simply count your digits 0,1 and then add a one to the next column. Hence, in the binary system the number zero in represented by a 0, the number one by a 1 and the number two by a 10, so forth and so on.

Here is a short table of some more examples:

Base 10 Base 2

0	0000
1	0001
2	0010
3	0011
4	0100
5	0101
6	0110
7	0111
8	1000

If you expand this table out, you will see, the maximum number of values you can represent with 4 binary digits(bits) is 16, with 16 bits, 65,536, with 24 bits, 16,777,216 and with 32 bits, 4,294,967,296. This is identical to being able to represent 10,000 (0-9999) values with four decimal digits and 100,000,000 (0-99,999,999)values with 8 decimal digits.

Macintosh address range

The original Macintoshes shipped with the 68000 microprocessor. While this CPU is capable of doing 32 bit operations, it has only 24 bit addressing capability. Which limits a 68000 based computer to 16,777,216 bytes of address range. When the Macintosh II came out with the 68020 which has full 32 bit addressing capabilities, the possible address range was increased to 4,294,967,296 bytes.

Now you're probably wondering why you can only access 8MB in 24 bit mode. The truth is you can access 16mb, but only 8mb is available for user data. The other 8 is used for hardware vectors, NuBus slots, SCSI buffers etc.

The Problem

Since the 68000 is a true 32 bit processor, it stores 32 bits of information for each memory address, but since the 68000 physically only has 24 address lines, only the first 24 bits actually count. This of course means that 8 bits are wasted.

This is where creative programmers come in. Back when the Macintosh only had a 128k of RAM, the Operating System had to go to some extreme lengths to ensure that application have enough memory to run. The Macintosh Memory manager allows blocks of memory to move, and/or be purged if the System is having trouble fulfilling a memory request. The original designers of the Macintosh OS decided to use the last three of the unused bits in a 32 bit memory address to indicate whether a block of memory can move, be purged or if the block contains a resource item.

When System 7 was introduced, the Memory manager portion of the Macintosh Operating system was modified extensively to support full 32 bit addressing. The Memory Manager no longer stores the movable, purgeable, or resource flags in the last three bits of the memory block's address, instead, the Memory Manager stores this information elsewhere. The exact location of these flags is not documented, since an application should not attempt to manipulate these flags directly.

Setting these three magic bits are at the discretion of the programmer. The Macintosh Operating System provides the programmer with the appropriate routines to set these bits. The problem is that to set these three bits, the Operating System routines have to call other routines who have to call still others etc. The net result is that using the Operating System routines to set these bits is quite inefficient when it comes to speed. Therefore, prior the introduction of System 7, some creative programmers with a need for speed, took it upon themselves to set these bits in the memory block's addresses directly thereby bypassing the overhead associated with calling the Operating System routines. Of course, the problem with

doing this is that System 7 no longer stores these three bits in the address of the block of memory. Another significant programming error involves the other 5 bits of the 32 bit address. Ordinarily, these bits should remain unused and therefore, insignificant. However, some programmers, having realized that 5 bits are wasted decided to use them for their own purposes, even though Apple Developer Technical Support began warning them against this practice a full three years prior to the introduction of System 7.

3. Why do I get Type 1 errors?

The fundamental problem with setting the upper 8 bits of the address directly is that with System 7 all 32 bits of information are used for addressing. Changing the value of any of the 8 bits changes the address of the block of memory. When an application or an init tries to access the block of memory that now has an invalid address, the usual result is a Type 1 error. This occurs because the first 24 bits of an address are used to access memory locations between 0 and 16mb. The upper eight bits are used to access memory locations between 16mb and 4,096mb. Since most Macintoshes have less than 16mb of RAM, chances are this incorrect memory location is pointing to an address that does not physically exist, and this will yield a Type 1 (Bus Error).

In the event that the memory location does physically exists, then the application or init will then operate on whatever information it finds at the incorrect location. Depending on what the application or init is attempting to do, various errors may result.

Pascal II: Library units

"Modular programming" is defined as the separation of procedures and functions, or groups of them, from the main program. Source language modules, called "units", are incorporated into libraries for use with Pascal programs. Units may consist of procedures and functions, or a combination of them written in Pascal or assembly language.

Compiling routines seperately--a necessary part of modular programming--affords you a major advantage in the development of your program: it allows you to approach the task as a group of smaller tasks linked together in a logical manner. The host program must contain a USES statement in order to use routines from the unit.
This article has been archived and is no longer updated by Apple.
The two principal kinds of units are called "Regular" and "Intrinsic".

NOTE: You are not afforded the capability of having separate units in Apple Pascal.

Regular Units:
When a host program "uses" a regular unit, the Linker physically inserts the unit's code into the host's codefile. Once linked, the files don't need to be relinked until either the unit or the host program is modified and recompiled.

Regular units, since they become part of the host file, may have references to file names. A regular unit may use an intrinsic unit or another regular unit.

NOTE: Regular units in version 1.0 of the Apple Pascal system are unable to use intrinsic units.

Install your Regular units in SYSTEM.LIBRARY or in any other library file. Once installed in an alternate library, the Uses statement should include the compiler option $U <library name> before the unit name.

Intrinsic Units:
An intrinsic unit is pre-linked--that is, it contains sufficient information to allow the host program to use it without invoking the Linker. The code for an intrinsic unit remains in the SYSTEM.LIBRARY and is loaded into memory before the host program begins its actual execution. This keeps the size of the host program down; it also allows you to modify and recompile the unit and host program individually without relinking them.

Intrinsic units must be installed in SYSTEM.LIBRARY. Intrinsic units may use other intrinsic units; they may NOT, however, use a regular unit.

NOTE: Intrinsic units may not reference files, such as data files, in Pascal version 1.0.

Assembly Routines as part of Units:
Assembly language routines may be placed into library units. With intrinsic units, the unit is compiled, the machine language routines are assembled, and then the assembled code is linked to the unit prior to installation of the unit into SYSTEM.LIBRARY.

Regular units may also contain machine language routines; however, these routines are not linked to the unit before it's installed in the library. Instead, the host program, the unit and the assembly routines are linked together at the same time.

Additional Notes on the Construction of a Unit:
Any unit which does not contain at least one procedure in the Interface section cannot have an Implementation section. In such a case, however, do include the initialization section--that is, the BEGIN and END.

Procedures listed in the Interface section are "public" to the host program as well as to the unit. Procedures listed only in the Implementation section cannot be accessed by the calling program; such procedures are called "private." When procedures are not listed publicly, they cannot be called from the host; furthermore, the Implementation section is not allowed.

Any intrinsic unit containing a global variable, either public ones (defined in the Interface) or private ones (defined in the Implementation), must have a data segment. If there is no data segment, a system error will occur.

General Format of Units:
The following example is designed to illustrate the general structure of a unit. The line numbers at the left of the page are for reference: they are NOT part of the actual structure.

```
1: (*$S+*)

2: UNIT < name >; INTRINSIC CODE xx DATA yy; (* DATA yy is used only if a data segment is required. *)
```

```
3: INTERFACE

4: USES < name of unit to be used >;
CONST < definitions >;
YPE < definitions >;

5: VAR < definitions >;

6: PROCEDURE ONE (I:Integer);
PROCEDURE TWO (I:Integer); (* External procedure *)
FUNCTION THREE (I:Integer) : Integer;
FUNCTION FOUR (I:Integer) : Integer; (* External function *)

7: IMPLEMENTATION

8: CONST < definitions >;
TYPE < definitions >;

9: VAR < definitions >;

10: PROCEDURE ONE;
BEGIN
END;

PROCEDURE TWO; EXTERNAL;

FUNCTION THREE;
BEGIN
END;

FUNCTION FOUR; EXTERNAL;

11: BEGIN
(* initialization section *)
END.
```

DISCUSSION

1: The swapping option is required when compiling ANY unit, regardless of its size. Omitting this option is the most common cause of compiler failures when working with units. The option should be the first line of text, preceding the UNIT header and any other compiler option.

2: The word INTRINSIC is required if the unit is to be intrinsic. DATA is optional, used only if a data segment is necessary (see #5 below). Regular units use only the UNIT < name > portion of this line.

3: INTERFACE is required. It defines the start of this section, which must contain some entries. (A totally empty INTERFACE section is not allowed.) This section contains the information which is public to both the host program and the unit (and visible from the LIBMAP program).

4: These entries are optional. If used, they are public (see #3). If a nested unit is used, it MUST be declared at this point, and the host program must also declare it in its USES statement before declaring this unit. (See pages 75-81 in the Pascal Language Reference Manual.)

5: VARs are also optional. If VARs are used in an intrinsic unit, a DATA segment MUST be declared, since these are global variables.

6: These are the public statements of the unit's procedures and functions. All parameters MUST be declared in this section, and must not appear in the IMPLEMENTATION. EXTERNAL may not be specified at this point (see #10).

7: IMPLEMENTATION is required. This section contains the code-generating statements and any private types or variables to be declared. If an item is declared in this section only, it is local to the unit and cannot be accessed from the host program directly; it is also not visible to LIBMAP.

8: CONST and TYPE definitions are optional. If included at this point, they are private and will not be visible to the calling program.

9: VARs are optional, and are private if defined at this point. A DATA segment is required if global VARs are specified in the IMPLEMENTATION section of an intrinsic unit, even though they are private.

10: These are the actual code-generating procedures. Procedures and functions already declared in the INTERFACE section need not have parameters listed here, since that would be redundant. EXTERNAL references are specified at this time.

11: This is the initialization section. Code in this portion is optional, but the BEGIN and END statements must always be present. The final END statement must be followed by a "." to indicate the end of the text. Code placed in the initialization section will be executed immediately upon access to the unit (through the USES statement in the host program), and ignored thereafter. An example of this is Turtlegraphics, where the initialization code is responsible for allocating the high-res page so that variables will not be lost.

System 7: How to Use 32-Bit Addressing (9/94)

How can I use 32-bit addressing and is it available on all Macintosh models?

This article has been archived and is no longer updated by Apple.
To take advantage of 32-bit addressing you must be running System 7.0 or higher. Many Macintosh models can enable 32-bit addressing in the Memory control panel.

Older Macintosh II models will need the 32-Bit System Enabler or MODE32 from Connectix to provide the capabilities of 32-bit addressing. Models that require this utility are the Macintosh II, IIx, IIcx, and SE/30. Other models, like the Plus, SE, and Classic can't use 32-bit addressing.

You would use 32-bit addressing if you have more than 8MB of physical RAM installed in your computer. Alternatively, you can use 32-bit addressing in conjunction with virtual memory to expand your memory to any arbitrary amount up to the available space on your hard disk. Remember, however, that Apple recommends the amount of virtual memory not exceed double the physical memory present in your Macintosh. Setting virtual memory higher causes significant performance degradation.

The Memory Control Panel lets you select between 24-bit operation and 32-bit (addressing) operation. Changes take effect when you restart. When you run in 32-bit mode, it's important that your applications be 32-bit-compatible. Most current releases of application software are compatible. Check with your software publishers for information about a specific product.

Follow these steps to run in 32-bit mode:

1) Open the Memory control panel.

2) Select 32-bit addressing.

3) Restart your computer to run in 32-bit mode.

Will my applications work with 32-bit addressing?

This article has been archived and is no longer updated by Apple.
Most applications are 32-bit-compatible and should work when your Macintosh is running in 32-bit mode. In 24-bit (the default) mode, the computer can run both 32-bit compatible and non-32-bit compatible software.

Those high-end users who specify the 32-bit addressing capability (through the Memory Control Panel) should ensure that their software is 32-bit compatible. Most current releases of application software are 32-bit compatible, and those that aren't should have upgrades available before too long.

This article has been archived and is no longer updated by Apple.
No. Your AppleShare File Server (version 2.0.1) is ready to use as is with System 7 clients. If you want to install System 7 on your server, then upgrade to version 3.0 of AppleShare.

If your server is connected with EtherTalk, you may want to upgrade the EtherTalk driver for Phase 2.

Do not upgrade the System Software on your AppleShare File Server (version 2.0.1) to System 7 unless you are also upgrading to AppleShare 3.0.

Can I attach a hard disk initialized under System 7 to my AppleShare 2.0.1 file server?

This article has been archived and is no longer updated by Apple.
Yes. You can take a hard disk that you have been using under System 7 and attach it to a Macintosh running AppleShare 2.0.x file server software. However, you must first rebuild its desktop, as follows:

1) Attach the hard drive to a Macintosh running System 6.

2) Restart the Macintosh.

3) Hold down the Command and Option keys while you restart.

4) The system will ask if you want to rebuild the desktop. Click OK.

Once the system completes its work, your desktop is rebuilt, and you can attach the hard drive to the AppleShare server.

Technical note: You need to rebuild the desktop because System 7 puts a desktop database on hard drives and this desktop database is not recognized by AppleShare 2.0. Rebuilding the desktop under System 6 creates the older-style desktop file.

Yes. Most third-party routers and gateways don't actually run on a Macintosh computer, so the system software version is irrelevant. What is relevant is whether the router or gateway supports AppleTalk Phase 2. In this area, all major router and gateway vendors offer products that support phase 2.

A partial list of major vendors includes 3Com, Alisa Systems, Engage Communications, Cayman Systems, Information Presentation Technologies, Focus Enhancements, Inc., Pacer Software Inc., and Shiva Corporation.

Should I install System 7 on my AppleShare Print Server?

This article has been archived and is no longer updated by Apple.
Not unless you have upgraded to AppleShare 3.0.

To use AppleShare PrintServer 2.0 with System 7 clients, you need to update only the LaserWriter drivers on the Print Server.

1) Quit the AppleShare PrintServer application and return to the Finder.

2) Insert System 7's "Printing" disk.

3) Drag two files from the "Printing" disk--LaserWriter and LaserPrep--into the System folder.

4) Double-click the AppleShare PrintServer application.

5) Optional: If your server also supports the AppleTalk ImageWriter II and/or the AppleTalk ImageWriter LQ, drag these drivers over too.

Your AppleShare PrintServer is now set up to work properly with all Macintosh computers using the 7.0 version of the LaserWriter drivers.

Note: Do not upgrade the system software on your 2.0.1 AppleShare PrintServer to System 7. If you want System 7 on the server, you will need to upgrade to AppleShare 3.0.

TA45335_System_The_Data_Access_Manager_(TIL06928).pdf

System 7: The Data Access Manager

What is the Data Access Manager?
This article has been archived and is no longer updated by Apple.
The Data Access Manager is a Macintosh system interface. It gives Macintosh application developers the flexibility of using a single, unified API for accessing data from different data sources. These sources include local Macintosh databases, remote Macintosh database servers, and even other remote host database servers, like DEC VAXes and IBM mainframes.

The Data Access Language (DAL) client/server API is a database extension in System 7 which provides access to remote host database servers. Applications written to the Data Access Manager can transparently use DAL to access data from DAL servers on host computers across different networks. The Data Access Manager is included along with the DAL client software in System 7.0.

The Data Access Manager offers three benefits:

* Macintosh applications now have a standard way to access data, regardless of the location of the data or the storage mechanism.

* Transparent access to the DAL client/server protocol is a part of the Data Access Manager.

* The architecture of the Data Access Manager is tailored for future extensibility.

The Data Access Manager provides two levels of interface for applications, a high-level interface and a low-level interface. The high-level interface is a standard way for all desktop applications, like a graphical charting package, to access data.

A new command has been added to the File menu: "Open Query". The end-user can pull down the File menu, select "Open Query", and choose a query like "Monthly Sales" to launch a request for data. This request returns the sales information for the month into an application, like a charting package.

The Data Access Manager's query builder makes it easier for in-house developers to create data-access pathways to different data sources. Thus, it delivers the flexibility to use such queries to create custom reports and presentations. The low-level interface is intended for in-house or custom developers who use tools like HyperCard and 4th Dimension to build highly-customized data-access interfaces. This low-level interface permits developers of data-intensive commercial applications, like statistical packages, to build sophisticated query interfaces for their desktop applications.

TA45336_System_Data_Access_Language_DAL_(TIL06929).pdf

System 7: Data Access Language (DAL)

What is Data Access Language (DAL)?
This article has been archived and is no longer updated by Apple.
Data Access Language, formerly called CL/1, is Apple's client/server protocol for remote data access and is based on ANSI standard SQL (Structured Query Language). DAL is optimized to provide decision-support applications with uniform access to data, regardless of the different brands of databases, the different host platforms, or the different types of networks.

DAL is intended for Macintosh applications that need ad-hoc access to data from multiple data sources. While performance-oriented applications, like transaction-processing applications, can use DAL, such applications, especially in a single database-vendor environment, could be better served by the many solutions available from third-party Macintosh database and tool vendors like Informix, The Ask Group, Inc./Ingres Products, Oracle, Sybase, and others.

DAL uniquely addresses the needs of customers with databases from multiple database vendors. The DAL client software is included as a part of System 7.0 and can be transparently accessed by applications written to the Data Access Manager API. These applications can access data from DAL servers running on host computers, across all DAL-supported networks. Therefore, with the Data Access Manager and the included DAL client software in System 7, applications can "speak" in an identical fashion to many different types of host databases.

Apple Computer Inc. is currently delivering DAL servers through APDA for the following environments:

* VAX/VMS (for DEC Rdb, Informix, Ingres, Oracle, and Sybase)
* MVS/TSO (for IBM DB2)
* VM/CMS (for IBM SQL/DS)

DEC also provides DAL as a part of the DEC PathWORKS product.

Apple is also working with software and hardware vendors to extend DAL client and server support to other industry platforms.

System 7: The Macintosh, DAL, and Database Development

What's Apple's database story?

This article has been archived and is no longer updated by Apple.
The Macintosh has always been the platform for unique and innovative applications--and this extends to the database world. Products like 4th Dimension (ACI), Omnis 5 (Blyth), Foxbase+/Mac (Microsoft Corp.) and Double Helix (Odesta) provide Macintosh users with state-of-the-art data management and application-development capability. In addition, all the major cross-platform, corporate-database, and application-tool vendors have also endorsed the Macintosh and delivered both client and server products, including ORACLE for Macintosh, ORACLE Server for A/UX (Oracle), Informix SE for A/UX (Informix), and Ingres Server for A/UX (The Ask Group, Inc./ Ingres Products).

Apple intends to continue to provide all the elements needed to make the Macintosh a complete platform for stand-alone and client/server database applications. Toward this end, Apple has announced various products, targeted at making the Macintosh the ideal database client platform. The Data Access Manager and the Data Access Language (DAL) client software included with System 7.0 further reinforce this position

These two products mean that Macintosh application developers can write their applications once and use the same applications to transparently access data in local or remote locations. With this infrastructure in place, Apple is working closely with third parties to provide its customers and developers with the database tools needed to implement mission-critical applications. To complete the database story, Apple and third parties are working together to make the Macintosh an equally strong platform for server applications.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

System 7: Data Access Language (DAL) vs. Data Access Manager

What is the difference between Data Access Language (DAL) and Data Access Manager?

This article has been archived and is no longer updated by Apple.
The Data Access Manager is a Macintosh System interface, while the Data Access Language is Apple's client/server API for ad-hoc remote data access. Applications written to the Database Access Manager API can transparently access data from remote host databases using DAL as the database extension. Both the Data Access Manager and the DAL client software are a part of System 7.0.

System 7: 6.0 DAL Apps Compatible with 7.0 Data Access Manager

Are my current 6.0 Data Access Language applications compatible with the 7.0 Data Access Manager?

This article has been archived and is no longer updated by Apple.

Yes. Special care was taken to ensure that current System 6 DAL applications will work smoothly with the Data Access Manager in System 7.

System 7: Benefits of the Data Access Manager

What can I do with Data Access Manager?

This article has been archived and is no longer updated by Apple.
With the new System 7 capabilities, you can benefit from the tight integration of data-access capabilities in all your Macintosh applications. You can pull data from your organizational databases directly into applications to work with as you desire, rather than the way it was delivered prior to System 7.

Will my locked, removable, System 7 volume mount under System 6?

This article has been archived and is no longer updated by Apple.
No. You must rebuild (or create) the desktop file on any cartridge not containing one from System 6 to bring it back into a System 6 environment. If this disk is locked or does not contain enough space for a resource desktop, System 6 won't mount the volume. You should unlock the volume to let a resource desktop be created.

A System 7 hard disk with not enough space could have the same problem and not mount under System 6.0. To work around this, remove some files under System 7 to let a resource desktop be created.

System 7: How to Start System 7 from a Floppy

Can I start System 7 from a floppy disk?

This article has been archived and is no longer updated by Apple.
System 7 will not fit on an 800K floppy. However, you can use the Installer to make a bootable 1.4MB floppy.

To create a bootable 1.4MB System 7 floppy, use the Customize option of the Installer to install the Minimum System for your Macintosh. This creates a bootable version that is very limited and contains minimal functionality for the Macintosh. Apple recommends that you not use this disk as your main system, but only as an emergency disk.

Bootable disks are also provided in both the System 7 800K and 1.4M disk suite on the "Disk Tools" disk. The 800K format contains a 6.0.X bootable system and the 1.4MB format contains a 7.0.X bootable system.

Custom installation lets you select the exact combination of system files, drivers, and other resources you want. You can use this process for initial installation, for updating to a new version of System software, for installing a single, special resource, or for saving space on your startup disk by eliminating software that isn't essential.

When you click "Customize" you have a choice of standard or minimal system files for each model of the Macintosh. Insert and select the 1.44MB floppy where you want to install System 7, choose the option Minimal for your Macintosh, then click Install.

System 7: Automatic Placement of Files in System Folder

Article Change History

08/24/92 - EDITED
* For clarity.

I dropped a file on my System folder; where did it go?

This article has been archived and is no longer updated by Apple.
When you drop a file onto the System Folder, the system automatically places the file in the right place in the System Folder. As a result, you shouldn't have to worry about where different things go in your System Folder. After the System places items in their appropriate locations, a dialog box will appear with a report of which folder(s) the items were dropped into.

You must put the file onto the icon for the System Folder for this automatic placement to work. If you drop the file into the open window of the System Folder, the system will not automatically place the file in the appropriate location.

* The system puts fonts into the System file.

* Control Panels go into the Control Panels folder.

* System extensions (formerly called INITs) go into the Extensions folder.

* Desk Accessories go into the Apple Menu Items folder.

If you want to put a system extension, control panel, font, or other item in another location within the System Folder, open the System Folder and drag the items directly where you want them to be.

What are the new sound capabilities in System 7?

This article has been archived and is no longer updated by Apple.
System 7 offers some exciting new sound capabilities that you will hear as software developers revise their applications for sound.

For the first time, a Macintosh with System 7 can play several sounds at once. For example, you could be playing a voice track and some other track at the same time. In addition, you can work on other things while the system plays a sound.

System 7 offers sound-input capabilities for the microphone included with recent Macintoshes. With sound-in, applications can start offering features like voice annotation of documents.

Finally, System 7 has built-in audio compression to save disk space, so you can have larger sounds than before.

Pascal: Error Numbers--Runtime Pascal

This article has been archived and is no longer updated by Apple.
Apple has a special version of Pascal for applications programs that doesn't require a Language Card: it's called Runtime Pascal. Any errors that the programmer doesn't catch will stop the program with an error number equal to the error number from page 280 of the Apple Pascal Operating system Manual plus 100. For example, a 'file not found' error would cause error 110.

This article has been archived and is no longer updated by Apple.
The field specifier in the WRITE statement allows you to fix the number of decimal places of a real number that will be printed; a field specifier of 0, however, won't work:

WRITELN (REAL:5:1); does

Pascal: Interrupts

This article has been archived and is no longer updated by Apple.
Pascal 1.1 will work with interrupts. Usually, interrupts are disabled when Pascal boots and the IRQ vector at $FFFE,FFFF points to the system re-initialization routine. You can write an assembly language routine that will point the IRQ vector to your interrupt handler, and thereby enable interrupts. Refer to the Language Card manual for how to write to the IRQ vector.

The disk routines in Pascal 1.1 are protected from interrupts during their time-dependant code. However, Pascal 1.0 doesn't protect its disk routines; interrupts are therefore not recommended in that environment.

* CCITT 1984 Compatible Mode
* Packet Assembler/Disassembler (X.3, X.28, X.29)
* Operation as a DTE
* Operation as a DCE
* Virtual Circuits: 64 maximum
* Single link for each Apple Serial NB Card
* Multiple cards for each Macintosh II
* Operation at up to 19.2Kbps with RS-232C
* Operation at up to 64Kbps with V.35
* Multiple servers for each AppleTalk network system

MacX25 does not support the following:

* Permanent Virtual Circuits
* X.32 switched circuit operation

Forms Creation Software: High-End Products

I want to create high-end forms. Claris' SmartForm is not powerful enough, nor does it have many of the features that a dedicated, high-end, forms processing and creation system has.

Are you aware of any high-end products for the Macintosh?

This article has been archived and is no longer updated by Apple.
Below are the names of three forms creation and management software publishers. Feature sets vary across the three. Each is strong in some areas and weak in others when compared to SmartForm from Claris. Apple is currently evaluating forms software for its own use. The project leader is very excited about features of packages not yet on the market. Great advances are expected in the next six months.

Here are the three packages and their publishers:

* Informed Designer from Informed Manager

* if/x: series from Softview

* True Forms from Adobe Systems, Inc.

For contact information, search the Technical Info library under the name of the publisher.

AppleShare PC 2.0: Using Expanded or Extended Memory

Is it possible to load AppleShare PC 2.0 into either extended or expanded memory?

This article has been archived and is no longer updated by Apple.
Yes, it is possible to load parts of AppleShare PC into extended memory (XMS) or expanded memory (EMS, EEMS, etc.) There is no real feature built into AppleShare PC to allow this, but a number of utilities exist that can manage memory and load programs and drivers into this alternate memory.

We have not done a great deal of testing with this, and, of course, third-party utilities that do this can't be treated as Apple-supported solutions. However, we have used one product (QEMM-386) to load a great deal of AppleShare PC 2.0.1 into extended memory on an IBM model 70 and it seems to work fine.

The process of determining what can and cannot be loaded into extended memory takes trial-and-error experimentation and can be rather complex. The variables involved include the processor capabilities of your computer, the capabilities of your memory-manager software, the number and type of programs to be loaded "high", and the type and amount of hardware that also needs use of this high memory range. This process is usually documented with the memory-manager software and differs enough between programs to be beyond the scope of this response. If you provide a very detailed description of specific PC installation, we may be able to provide more assistance.

For information on the QEMM-386 package, please contact the manufacturer, Quarterdeck Office Systems. For contact information, search the Technical Info library under "Quarterdeck".

Note: At the time we tested it, QEMM-386 v5.1 was the one third-party memory manager available that was a compatible substitute for the Windows 3.0 HIMEM.SYS memory manager. There are now several other utilities, some commercial, some user-supported, advertising this ability. We have not tried any of these and probably won't unless a specific case needs attention.

DAL: DB2 Data Updates Concerns

We have developed the first phase of an enterprise-wide DSS system using DAL up to a DB/2 database. We need to query information and do real-time updates to the database.

From the query standpoint, everything works fine, but I have some concerns regarding updating the host database. Overall, we want to set up standards and procedures for updating DB/2 data from Macintoshes. Dynamic SQL gives us the capability to update the host, but MIS may not allow its use, due to backup, recovery, security, and other control issues. As alternatives to dynamic SQL, we could use batch mode on the host or COBOL to do the updates.

This is more of an organizational issue than a strict technical problem. Has anyone else faced the same issues, developed guidelines, and so on?
This article has been archived and is no longer updated by Apple.
The fact that DAL uses dynamic, not static, SQL is not really the issue. You need to establish security by user or user group regardless of the kind of SQL used to access the tables.

The problems and concerns with backup and recovery are a function of the DB2 design and would exist if you used static SQL and CICS to do transaction updates. If you want neat backup points (for possible recovery later), you will have to do your updates in batch programs with quiesce points before and after. We are not aware of any guidelines established to address this issue.

Applesoft: Random numbers

All numbers produced by running Applesoft's random number generator follow the same sequence as the first RUN, since the Applesoft's random number seed is not reinitialized.

This seed number, stored in locations $C9 to $CD, is initialized when your system is first booted.
This article has been archived and is no longer updated by Apple.
The Applesoft random number generator is only a pseudo-random generator (as are most generators); thus, non-random patterns eventually occur. The frequency these patterns repeat varies from program to program, though proper re-seeding of the random number generator helps prevent small repeating sequences.

Here are two suggestions:

1. Use the monitor's random seed at locations 78 and 79 to initialize Applesoft's random number seed. Since the monitor's seed is constantly incrementing while waiting for a key to be pressed, you'll start on one of 65536 different sequences.

```
10 X = RND (-PEEK (78) - PEEK (79) * 256)
```

2. This random sequence can be lengthened by re-seeding the generator occasionally within the application program by adding the statement X = RND (-RND (1)).

No method completely eliminates patterns in the random numbers generated, but you can lengthen the sequences until they're difficult to detect.

Applesoft's algorithm is:

1. Multiply the random seed by 11879546.4.
2. Add the result to 3.92767778 E-08.
3. Swap the most and least significant bytes of the result.
4. Force the exponent into the 0..1 range.

The example below shows the effect of the algorithm on a number. The most and least significant two decimal digits are swapped instead of bytes in this example:

```
0.500000000
* 11879546.4
-----------
5929773.2
+ 0.0000000392767778
------------------------
5929773.2 (the rest is lost)
-- --- swap "bytes"
3229775.9

0.32297759 force value between 0 and 1
```

WebObjects 4: Java FAQ

This article contains frequently asked questions (FAQ) regarding WebObjects 4's support for the Java programming language, with answers to those questions.
This article has been archived and is no longer updated by Apple.
Questions answered in this article:

1. What JDK version is used in WebObjects?
2. Can I use a different Java version?
3. Does Apple support Just-in-Time (JIT) compilation with WebObjects 4?
4. How do I debug Java code in ProjectBuilder?

Question 1: What JDK version is used in WebObjects?

Answer: WebObjects 4 uses Sun's 1.1.6 JDK. This is the only version officially supported by Apple. In addition, WebObjects 4 supports Sun's Swing interface library, version 1.0.3.

Question 2: Can I use a different Java version?

Answer: You may be able to run later versions of Java by simply pointing the JDK environment variable to the new version and modifying your JavaConfig.plist file; however, Apple will not provide support for any version of Java other than the one which shipped with WebObjects 4. Because WebObjects is designed to work with Sun's Java VM, Microsoft's Java VM will not work with WebObjects.

For an unsupported procedure that can be used to update the WebObjects JDK version, see **article 70064**.

Question 3: Does Apple support Just-in-Time (JIT) compilation with WebObjects 4?

Answer: JIT functionality is not available in this release of WebObjects. WebObjects applications spend much of their time running compiled framework code; the speed benefits of this approach are greater than would be seen with JIT-compiled Java code.

Question 4: How do I debug Java code in ProjectBuilder?

Answer: WebObjects 4's Project Builder includes a Java debugger based on Sun's jdb. For more information on debugging Java code, see the appropriate section of the WOInfoCenter.

EOF 2.2 Patch 1 Overview

Some versions of this patch are now **obsolete**. This patch should **only** be installed on OPENSTEP for Mach and HP-UX systems running EOF 2.2 or WebObjects 3.5.1. For Solaris and Windows NT systems, install **EOF 2.2 Patch 2** instead.

The WebObjects Current Patch List, **TIL article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read these documents if you're not sure which patches you need on your system.
This article has been archived and is no longer updated by Apple.

About This Patch

This document contains release notes for EOF 2.2 patch 1, an update to Apple's Enterprise Objects Framework on all supported platforms. Customers who are interested in upgrading from EOF 2.1, the version of EOF included in OPENSTEP Enterprise 4.2 and packaged separately for the Mach operating system, should contact Apple Enterprise Support for more information, through an authorized Apple Support contact or by emailing **support@enterprise.apple.com**.

Installing EOF 2.2 Patch 1 on OPENSTEP 4.2 for Mach

1. Download the Mach version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/patches/

2.2/EOF2.2_Mach_Patch1.pkg.tar
```

2. Uncompress the Mach package file. Your web browser or FTP client may perform this step for you.

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Double-click on the EOF2.2_Mach_Patch1.pkg file. Make sure that no EOF-based applications are running before you perform this step.

5. Click the Install button in the Installer package window. An Install Package panel will open.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, **click OK** to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

Installing EOF 2.2 Patch 1 on Windows NT 4.0

1. Download the Windows NT version of the patch fromApple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/EOF2.2_NT_Patch1.TAR.gz
```

Also **download** the installer script, "patcher.nt.sh" from:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/

patches/patcher.nt.sh
```

2. Log in as a user with Administrator privileges.

3. Open a Bourne shell. The Bourne shell should be available from your Start menu, under the WebObjects program group, or under your Apple root directory at Demos\\sh.exe.

4. Change to the directory containing the patch and the patch installer, "patcher.nt.sh".

5. Type the following at the shell prompt (make sure that there are no EOF applications running first):

```
patcher.nt.sh -install EOF2.2_NT_Patch1.TAR.gz
```

For more information on using the patcher.nt.sh program, type the following at the command prompt:

```
patcher.nt.sh -help
```

6. Reboot your Windows NT system

Installing EOF 2.2 Patch 1 on Solaris or HP-UX

1. Download the Solaris version or the HP-UX version of this patch from Apple's FTP servers at ftp.info.apple.com. The files are located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/EOF2.2_Solaris_Patch1.TAR.Z
```

and

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/

patches/2.2/EOF2.2_HPUX_Patch1.TAR.Z
```

Also download the installer script, "patcher.sh" from:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/

patches/patcher.sh
```

2. Log in as root. If you're not sure how to log in as root, see your system administrator.

3. Change to the directory containing the patch and the patch installer, "patcher.sh".

4. Type the following at the shell prompt (make sure that there are no EOF applications running first):

```
patcher.sh -install EOF2.2_Solaris_Patch1.TAR.Z
```

or

```
patcher.sh -install EOF2.2_HPUX_Patch1.TAR.Z
```

For more information on using the "patcher.sh" program, type the following at the command prompt:

```
patcher.sh -help
```

5. Reboot your Unix system

Issues Fixed

Corrected in EOF 2.2 Patch 1

Sybase Adaptor Issues

Incorrect Sybase smallint mapping
Apple reference # 2247522, 2241377

ISSUE:
On HP-UX and Solaris, data of type **smallint** would be mapped incorrectly when retrieved from a Sybase database. Instead of being mapped to **NSNumber/Short**, the data would be mapped to **NSNumber/Integer** and assigned the original value times 2 ^16.

RESOLUTION:
The Sybase adaptor now correctly maps smallint data to type NSNumber/Short.

All parameters required for Sybase stored procedures
Apple reference # 2203081

ISSUE:
If you did not supply all values when executing a Sybase stored procedure, the execution would fail with an exception like:

```
Feb 19 11:23:53 WOF_3_5_Sybase_Patch[1027] Caught exception:EOGeneralAdaptorException
Sybase: Server:unknown Procedure:NEXT_MOVIE_PRIMARY_KEY Line:0 Procedure NEXT_MOVIE_PRIMARY_KEY expects
parameter @A_MOVIE_ID, which was not supplied.
```

This happens even though A_MOVIE_ID is not required for the stored procedure.

RESOLUTION:
The Sybase adaptor no longer requires optional arguments to stored procedures.

Cannot fetch float-NSDecimalNumbers along with text columns
Apple reference # 2208497

ISSUE:
If you have an attribute with external type float, and internal type NSDecimalNumber, it will not fetch properly if a text column is also in the fetch. The attribute will be blank.

RESOLUTION:
The Sybase adaptor now correctly fetches these attributes.

Special characters crash Sybase adaptor
Apple reference # 2261262, 2260785

ISSUE:
The SybaseEOAdaptor would crash when saving Text or BLOB data containing characters which could not be encoded using the specified database encoding.

RESOLUTION:
The adaptor has been fixed to detect the encoding failure and raise an exception, so that a database encoding which is able to handle the issue characters may be specified in the connection dictionary.

Sybase can't fetch float and text data together
Apple reference # 2274601, 2259088

ISSUE:
The Sybase adaptor would not fetch data of types text and float together.

RESOLUTION:
The adaptor has been fixed. There is no longer a conflict between these data types.

Can't use smallints as arguments to Sybase stored procedures
Apple reference # 2274608, 2262888

ISSUE:
The Sybase adaptor did not allow the use of smallints as arguments to stored procedures.

RESOLUTION:
The Sybase adaptor now allows stored procedures with smallint arguments.

Can't use Sybase 11 stored procedures
Apple reference # 2274650, 2244533

ISSUE:
The Sybase adaptor was unable to interpret stored procedures created in Sybase 11.

RESOLUTION:
The adaptor has been fixed to work properly with stored procedures from both Sybase 10 and Sybase 11.

Incorrect time zone conversions
Apple reference # 2276907, 2276899

ISSUE:
When converting a time value to the server time zone, the Sybase adaptor would substitute the server's time zone without actually adjusting the time value for the zone difference.

RESOLUTION:
The Sybase adaptor now performs the conversion of the time value to the corresponding value in the server's time zone.

Oracle Adaptor Issues

Oracle adaptor state not preserved
Apple reference # 2252175

ISSUE:
If the Oracle adaptor encountered an error while closing the database channel, the adaptor state would not be set correctly. As a result, the database connection could not be reestablished on that channel once the database came back up.

RESOLUTION:
The Oracle adaptor now sets its internal state correctly before raising the error, allowing the connection to be re-established once the database is restored.

Optimistic locking fails on rows with trailing spaces
Apple reference # 2231704, 2177721

ISSUE:
EOOracleAdaptor would strip trailing spaces from VARCHAR2 data fetched from or committed to an Oracle database, causing optimistic locking to fail if a database row contained trailing spaces inserted by another tool.

RESOLUTION:
EOOracleAdaptor no longer strips trailing spaces from VARCHAR2 data.

Oracle adaptor generates incorrect SQL for left and right outer joins
Apple reference #2288089, 2165674

ISSUE:
The SQL generated by the Oracle adaptor for a left outer join was actually the syntax for a right outer join, and vice versa.

RESOLUTION:
The Oracle adaptor now generates the correct SQL for left and right outer joins.

Informix Adaptor Issues

Informix adaptor crashes on failed referential integrity check
Apple reference # 2274351, 2272207

ISSUE
If the Informix adaptor was unable to find matching source and destination entities of a referential integrity constraint, it would pass a nil pointer to the database. This would cause a crash in the Informix adaptor.

RESOLUTION
The Informix adaptor now tests for this condition and handles it appropriately.

ODBC Adaptor issues

ODBC Adaptor cannot execute stored procedures with output parameters
Apple reference # 2208503

ISSUE
The EOF 2.2 (WebObjects 3.5) version of ODBCEOAdaptor.framework introduced a bug which causes an error when using a stored procedure with an output parameter.

RESOLUTION
The ODBC adaptor now handles output parameters correctly.

ODBC adaptor leaks connections with Microsoft Access
Apple reference # 2209574

ISSUE:
The EOF 2.2 (WOF 3.5) and earlier versions of ODBCEOAdaptor.framework did not release ODBC connections when using Microsoft Access (or any JET based data source) in order to work around a bug in the Microsoft odbcjt32.dll library; this bug caused a crash when SQLFreeConnect was called. The SQLFreeConnect bug was discovered in version 3.40.2829 of the DLL. Newer versions of the DLL (beyond 3.50) no longer exhibit the crashing issue.

RESOLUTION:
The patched version of this framework now checks the version of the DLL more carefully and allows SQLFreeConnect to be called unless the DLL version is 3.4X. The adaptor no longer leaks the ODBC Connection when running with fixed versions of odbcjt32.dll.

Tools And Frameworks Issues

Development tools may attempt to load EOModel file twice for an application nested within an aggregate project
Apple reference # 2267783, 2176591

ISSUE:
When an application was nested in an aggregate project, the development tools would sometimes attempt to load an EOModel file twice due to an error in the path searching code.

RESOLUTION:
The search path has been corrected in this version. The development tools now handle subprojects of aggregates correctly.

Nil value in EOAttribute causes crash while saving EOModel
Apple reference # 2274226, 2220588

ISSUE:
A crash would sometimes occur during the save of an EOModel because a nil serverTimeZone attribute was being inserted into the EOModel.

RESOLUTION:
The EOAccess layer has been changed to test for and handle a nil value for this attribute.

EOWizard not localizable
Apple reference # 2231705, 2177282

ISSUE:
EOWizard was not localizable.

RESOLUTION:
Template files have been moved from the framework's Resources directory to the ../Resources/English.lproj directory, making it possible to localize these resources.

Exception while writing model to disk corrupts EOModel
Apple reference # 2274225, 2220893

ISSUE:
If an exception was raised while an EOModel was being written to disk, the original model would be lost and only the partially-written or corrupted model was left on the disk.

RESOLUTION:
A backup copy of the EOModel is made before the write begins. If an error occurs during the write, the backup EOModel will now be restored to the disk, and a copy of the partially written new EOModel will also be saved (as <model_name>.eomodeld#).

BusinessLogic framework fails to retain some global IDs
Apple reference # 2290236, 2290233

ISSUE:
Several classes in the BusinessLogic framework example failed to retain global IDs for some enterprise objects, resulting in messages being sent to

unexpectedly freed objects.

RESOLUTION:
The classes now retain global IDs appropriately.

EOAccess Issues

EOEntity methods raise exceptions
Apple reference # 2256685, 2251180

ISSUE:
Under some circumstances some methods of EOEntity, including setAttributes, setClassProperties, setRelationship, and removeRelationship, would not clear a private variable, potentially resulting in an application exception.

RESOLUTION:
These methods now handle their private instance variables correctly.

Prefetching can mysteriously fail
Apple reference # 2264033, 2223730

ISSUE:
Prefetching would sometimes fail for no apparent reason, due to inappropriate filtering of relationships inside the EOAccess layer.

RESOLUTION:
The incorrect filtering on prefetches has been removed from EOEntity.

Unnecessary firing of to-many faults
Apple reference # 2248080, 2227660

ISSUE:
If the PropagatePrimaryKey flag on an EOEntity was set to YES, saving changes to the EOEditingContext would fire array faults for all of that entity's to-many relationships. This was not necessary and could cause performance issues.

RESOLUTION:
The EOAccess layer has been changed so that it no longer fires unnecessary faults.

Multiple propagation primary keys create race condition
Apple reference # 2267964, 2260541

ISSUE:
Saving changes to two databases when both had a propagation primary key would not work in previous versions of EOF; a race condition would be created, and only one database would be able to generate primary keys.

RESOLUTION:
EODatabaseContext has been changed to correct this behavior. Both databases can now generate their primary keys correctly.

EODatabase never releases snapshots
Apple reference # 2231693, 2169671

ISSUE:
Snapshots associated with enterprise objects were never released.

RESOLUTION:
EOF now tracks an object's snapshots and releases them when all objects that refer to them are released.

Deallocating an EODatabase containing snapshots causes crash
Apple reference # 2272549, 2265751

ISSUE:

EODatabase released its snapshots too early during deallocation. As a result, deallocating an EODatabase would raise a fatal exception if any snapshots were present.

RESOLUTION:
The order in which instance variables are released by EODatabase has been corrected.

Logic error in EOAccess layer sometimes raises exception while generating primary keys
Apple reference # 2278561, 2182084

ISSUE:
Under certain circumstances, the EOAccess code that generated primary keys would send messages to inappropriate objects. This would cause a "NoSuchMethodError" exception to be thrown in Java, or one of several exceptions to be raised in Objective C.

RESOLUTION:
EOAccess now checks the class of the receiver before sending the message that was causing the issue.

Incorrect NSNumber formatting for zero values
Apple reference # 2264031, 2181645

ISSUE:
Zero values for number fields displayed by EOF would not always reflect appropriate formats for zero; some integer zero values would be represented as "0.00".

RESOLUTION:
EOEntity has been modified to check the default zero formatting for all number types.

Deleting objects with "toManyToOne" relationships sometimes fails.
Apple reference #2287021, 2278795

ISSUE:
In some circumstances, EOF would not correctly handle deletion of an object with a toManyToOne relationship, leaving rows in intermediate tables which should have been deleted.

RESOLUTION:
The EOAccess layer now does a more thorough analysis of an object's relationships when it is deleted, and data in intermediate tables is correctly removed.

Editing the owning relationship in a nested editing context more than once corrupts the database snapshots.
Apple reference #2287025, 2280979

ISSUE:
Due to an error in the processing of array faults by the databse context, editing the owning relationship in a nested editing context more than once would corrupt the database snapshot for the owning object, resulting in database corruption.

RESOLUTION:
The error in EODatabaseContext has been corrected.

Incorrect time zone conversion in EOAccess layer.
Apple reference #2287379

ISSUE:
When converting a time value to the server time zone, the EOAccess layer would substitute the server's time zone without actually adjusting the time value for the zone difference.

RESOLUTION:
EOAttribute now performs the conversion of the time value to the corresponding value in the server's time zone.

EOControl Issues

EOModeler can't create a model with EODeleteRuleNoAction
Apple reference # 2248443, 2202107

ISSUE:
In EOModeler's AdvancedRelationship inspector, if the Delete Rule was set to "No Action", the following warning would be posted next time the model was opened:

```
Invalid delete rule string:'EODeleteRunNoAction' on entity with name: '<entity_name>'
```

RESOLUTION:
It is now possible to create a model in EOModeler with EODeleteRuleNoAction.

Newly inserted objects not deleted correctly
Apple reference # 2253191, 2176466

ISSUE:
An object created and inserted into an editing context or relationship, then deleted before being saved to the database, would not be completely removed. This would raise an exception when the editing context was saved.

RESOLUTION:
Deletion of a newly-inserted object now completely removes the object from the editing context.

EOQualifier qualifierWithFormat methods conflict
Apple reference # 2275802, 2203613

ISSUE:
If a qualifier was created using **+[EOQualifier qualifierWithQualifierFormat: arguments:]** and, subsequently, another qualifier was created using **+[EOQualifier qualifierWithQualifierFormat:]**, a parse error would occur, even if the second qualifier was valid.

RESOLUTION:
The interference between these two methods has been removed and they now operate correctly.

Java garbage collecting fails with EOEditingContext
Apple reference # 2270489, 2264063, 2264251

ISSUE:
The editing context did not retain its registered objects. This would cause issues with Java garbage collection.

RESOLUTION:
EOEditingContext now allows users to specify whether editing contexts retain their objects or not with the new class methods **setInstancesRetainRegisteredObjects:flag:**, **getInstancesRetainRegisteredObjects**, and **reset**. For API details, please see EOEditingContext.h. By default, in applications which contain Java, the editing context will retain all registered objects.

EOControl raises exception while building qualifier
Apple reference # 2271206, 2213188

ISSUE:
The qualifier parsing code in the EOControl layer incorrectly sends **copyWithZone:** to custom enterprise objects under certain conditions, causing a "selector not implemented" exception to be raised in Objective C or a "CloneNotSupportedException" to be thrown in Java.

RESOLUTION:
EOControl no longer calls **copyWithZone:** on custom enterprise objects when building a qualifier.

Uppercase letters in search pattern don't case-insensitive match to lowercase string
Apple reference # 2275805, 2248977

ISSUE:
Case-insensitive matching in EOQualifier did not correctly match uppercase letters in the search pattern with lowercase letters in the receiving string.

RESOLUTION:
EOQualifier has been fixed. **[EOQualifier isCaseInsensitiveLike:]** now works correctly.

Can't subclass entities with fetch specifications
Apple reference # 2279849, 2278492

ISSUE:
Due to an error in EOKeyValue encoding, EOModeler was unable to create a subclass when a fetch specification was associated with the entity being subclassed.

RESOLUTION:
The encoding is now correct and entities with associated fetch specifications can be subclassed from within EOModeler.

EOFault's retain/release behavior confuses the Java bridge
Apple reference # 2297785, 2239504

ISSUE:
EOFault's special handling of retain and release could sometimes cause conflicts with the Java bridge.

RESOLUTION:
EOFault's retain and release behaviours have been modified to interoperate correctly with Java via the bridge.

EOInterface Issues

No EOActionCellAssociation for most controls
Apple reference # 2269874, 2243956

ISSUE:
EOActionCellAssociation would not work with controls other than NSTextField.

RESOLUTION:
This class has been changed to work with NSButtons and other controls, as well as NSTextFields.

selectObject: method return values don't match documentation
Apple reference # 2275804, 2205357

ISSUE:
The **[EODisplayGroup selectObject:]** method would only return 'NO' if it could not end editing or if the delegate refused the change. According to the class documentation, it should also return 'NO' if the EODisplayGroup's displayedObjects array does not contain a match with the method's object argument.

RESOLUTION:
As stated in the documentation, this method now also returns 'NO' when it cannot find a match for the argument object.

Memory leak in EODisplayGroup
Apple reference # 2256402, 2217263

ISSUE:
A private variable was not being released in EODisplayGroup, causing a memory leak.

RESOLUTION:
This variable is now released correctly.

EODisplayGroup instances leak
Apple reference #2286314

ISSUE:

Each EODisplayGroup instance leaked two EOObserverProxy objects.

RESOLUTION:
This leak in EODisplayGroup has been fixed.

OPENSTEP 4.2 and Third Party Libraries

This article describes how to link an OPENSTEP Enterprise 4.2 application against a third-party C library; in this case, the Lightweight Directory Access Protocol (LDAP) library from Netscape.
This article has been archived and is no longer updated by Apple.
On Windows NT, shared libraries are stored as dynamically loaded libraries (.DLL) files. To link against a third-party DLL, you also need the associated .LIB file. The .LIB file contains the actual entry point relocations into the DLL. Compiling and linking requires only the header (.h) and .LIB files. At run time, install the .DLL in a directory that appears in your system's PATH environment variable.

The necessary third party files to link against the LDAP library can be downloaded from Netscape at http://devedge.netscape.com/one/directory/. For this example we downloaded dk11e32.exe, which is a self-extracting file. The LDAP files were installed in the following locations:

- nsldap32v11.lib in c:/OpenStep/Lib
- ldap.h in c:/OpenStep/include (as well as the other LDAP headers)
- nsldap32v11.dll in c:/Next/NextLibrary/Executables

To use LDAP, you will also need to set the following environment variables:

- PATH should include c:/NextLibrayr/Executables
- INCLUDE should include c:/OpenStep/include

In ProjectBuilder, add **nsldap32v11.lib** to the "Libraries" suitcase and import the ldap header in one of your project's existing header files. You will now be able to access the functions of the LDAP library.

Below is source code from a simple test app. This application will display its version number (110) in a text field when a button is pressed. Note that for this simple test case, no attempt was made to configure an LDAP Directory server.

```
//========= AppControl.h ========================================

#import <AppKit/Appkit.h>
#define LDAP_API(rt) rt          // <== this did the trick in the test app!
#import <ldap.h>

@interface AppControl : NSObject
{
   id pTextField01;                                  //<==== pointer to text field
}

- (void)clickedCallLDAP:(id)sender;  //<=== action method - called when
                                     //
button is clicked

@end

//================================================================

Notice that b efore importing the Netscape  ldap.h  file  in AppControl.h above,
the following define occurs:

   #define LDAP_API(rt) rt

Without this line LDAP_API will get set this way (in ldap.h):

   #define LDAP_API(rt) __declspec( dllexport ) rt
```

This definition will generate wrong linker symbols that will not be found in the library. The result is linker errors (error LNK2001: unresolved external symbol ....). Below is the implementation file.

```
//============ AppControl.m ======================================

#import "AppControl.h"

@implementation AppControl
```

```
- (void)clickedCallLDAP:(id)sender
{
 LDAPVersion ver;
 double SDKVersion;

 SDKVersion = ldap_version( &ver );              //<=== get version number

 printf("LDAP version = %7.3f\\n", SDKVersion);
 [pTextField01 setIntValue:SDKVersion];        //<=== display in text field
}

@end

//================================================================

Macintosh IIsi and Display Card 824 GC: Compatibility Update

What recommendations can you make regarding 8*24 GC card and the Macintosh IIsi?

This article has been archived and is no longer updated by Apple.
The Macintosh Display Cards 4*8, 8*24, and 8*24 GC can be used in any NuBus-capable Macintosh. This includes the Macintosh II, Macintosh IIcx, Macintosh IIx, Macintosh IIfx, Macintosh IIci, Macintosh IIsi with NuBus adapter card, and the Macintosh Quadra computers.

There have never been any concerns regarding the Display Cards 4*8 and 8*24 and the Macintosh IIsi. These have been and continue to be recommended configurations.

The Display Card 8*24 GC takes slightly more power, due to the processor and on-board memory, than the NuBus power specification of 15 watts. Because Apple had not completed initial testing of the Macintosh IIsi and Display Card 8*24 GC combination in October 1990, we were not able to initially recommend the combination.

We have now completed initial tests and can now recommend the Macintosh IIsi and Macintosh Display Card 8*24 GC combination in normal operating environments, meeting Apple's high reliability requirements.

Apple is continuing testing for elevated temperature environments. We will publish results of these tests as they become available. Until then, we do not recommend the combination of Macintosh IIsi and Macintosh Display Card 8*24 GC in environments where the temperature is expected to regularly exceed 32 C or 90 F. But we can recommend the combination for normal environments.

With regard to third-party cards, we have found the vast majority to be completely compatible and to work reliably with the Macintosh IIsi. In those few instances where the power specification exceeds the NuBus specification, or if you have any questions or concerns about a specific product, contact the vendor. In Apple's case, we can now recommend all of our displays cards across the line of NuBus-capable Macintoshes.

OPENSTEP 4.x Driver: Adaptec 78xx SCSI

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.

NOTE: Apple Enterprise Software has suspended on-going development of new drivers for the NeXTSTEP and OPENSTEP product lines. Where possible, we will be updating current drivers for minor product revisions. These drivers will be made available in the TIL.

For a complete list of supported drivers for the OPENSTEP operating system, see the **OPENSTEP Driver Compatibility Guide**.
This article has been archived and is no longer updated by Apple.
Availability Information

A **beta version** of this driver, version 4.01, is avaiable on Apple's FTP servers

Driver Name / Installer .pkg: Adapec78XXSCSI

Driver Type: SCSI

Driver Scope: Generic-Chipset

PC Bus / Interface Supported by Driver*: Integrated, PCI

General Overview notes:

The Adaptec 78XX Series driver is designed to support the AHA-2940 Dual Channel series of PCI SCSI adaptors.

Supported Products / Add-on Adapters:

Adaptec AHA-2940 UW Dual (PCI, Ultra/Wide SCSI, dual channel)

Special Features of Driver / Driver Notes:

This driver should also support (but has not been tested with) all of the adaptors listed for the Adaptec 2940 driver.

SCSI Driver Details

Supported Connectors: 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2), 68-pin High Density (Wide SCSI)

Access Mode: Bus Master DMA

Attributes*: SCSI-2

WebObjects 4.0: Windows NT NSTimeZone Bug Workaround

The workaround described in this article has been included in WebObjects 4.0.1. Apple recommends that all WebObjects 4.0 users upgrade to WebObjects 4.0.1. This obsolete article is provided here as a convenience to our customers who have not yet upgraded.
This article has been archived and is no longer updated by Apple.
There are two known problems with the NSTimeZone object in the Windows NT release version of WebObjects 4.0. This document discusses how to recognize these problems and provides a workaround that corrects them. These problems do not affect the Solaris or HP-UX versions of WebObjects 4.0. The problem has also been corrected in WebObjects 4.0.1.

New NSGregorianDate with new NSTimeZone raises exception
Apple reference # 2296907

PROBLEM:
Using the NSGregorianDate constructor to generate a new date with a new NSTImeZone would generate an exception; for example, calling:

```
NSGregorianDate getADate = new NSGregorianDate(1999, 12, 25, 12, 15, 00, new NSTimeZone("EST", true));
```

would generate the error:

```
NSInvalidArgumentException: *** -[NSConcreteTimeZone _initWithJavaHandle:]:
```

timeZoneWithName returns nil value
Apple reference # 2293191

PROBLEM:
The NSTimeZone timeZoneWithName method would always return a nil value.

RESOLUTION:
Both of these problems can be resolved by replacing your system's WindowsName.table file, located in:

```
$NEXT_ROOT/Library/Frameworks/Foundation/Resources/TimeZoneInfo/WindowsName.table

Back up your old WindowsName.table file, then download the updated file:
```

WindowsName.table.zip

Unzip this file, make sure the filename is WindowsName.table, then replace the original file with the version you've just downloaded. Your do not need to restart Windows NT for this workaround to take effect.

WebObjects 4.0 Install Documentation

This document explains where to find the WebObjects 4 installation documentation.
This article has been archived and is no longer updated by Apple.
Q: Where is the WebObjects 4 installation documentation? I can't find it in the WOInfoCenter!

A: The installation documentation is not included in the on-line documentation installed with WebObjects. Instead, it can be found on the top level of your WebObjects installation CD, in .pdf format.

OPENSTEP 4.2 for Mach Patch 2 Overview

This patch is now obsolete. Please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.

About This Patch

This patch is obsolete; please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This patch contained a number of important bug fixes, including corrections for some Year 2000 problems, improved support for the Euro currency symbol and support for large hard drives on OPENSTEP systems. In addition, this patch included a new VESA video driver that provided support for a wide range of display hardware on OPENSTEP systems. For more information on these topics, please see the sections "New Features" and "Problems Fixed" below.

Installing OPENSTEP 4.2 for Mach Patch 2

1. **Download** the Mach version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/

patches/4.2Mach_Patch2.compressed
```

2. Uncompress the Mach package file. Your web browser or FTP client may perform this step for you.

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Double-click on the 4.2_Mach_Patch2.pkg file. Make sure that no OPENSTEP applications are running before you do this step.

5. Click the Install button in the Installer package window. An Install Package panel will open.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, **click OK** to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

New Features

New in OPENSTEP 4.2 for Mach Patch 2

VBE VESA Driver

This patch installs a VBE video driver. This driver allows an OPENSTEP 4.2 system to use any display adapter which conforms to version 2.0 of the VESA BIOS extension standard. Use of the VBE driver requires updating the kernel and the booter. The updated kernel and booter are also compatible with all other video drivers, and both are included in this patch. For more information, see the VESA VBE OPENSTEP Driver Overview, **TIL article 70026**.

New Booter Features

The new booter included in this patch includes two new features:

1. If you are using the new VESA VBE driver, you can **specify a VBE video mode at boot time**. Specify **"VBE Check"=Yes** at the boot prompt to get a list of available VBE video modes. Then use **"VBE Mode"=xxx** to specify the mode number you want to use. The mode number is the three-digit number listed before each mode. For example, if one of the listed video modes was:

257=640x480x256

you would type **"VBE Mode"=257** at the booter prompt to boot with 640x480, 256-color VESA graphics.

2. The new booter allows you to **step through your boot drivers**, choosing which to load and which to skip. Specify **Query=Yes** at the boot prompt, and the booter will prompt before loading each boot driver.

Problems Fixed

Corrected in OPENSTEP 4.2 for Mach Patch 2

No Euro symbol support in OPENSTEP
Apple reference # 2265776

PROBLEM:
OPENSTEP 4.2 for Mach did not include Euro currency symbol support.

RESOLUTION:
Support was added for the Euro currency symbol. Typing a Euro currency symbol character will require a modified keyboard keymapping. The currency character is encoded as symbol 0xA0 in the keyboard symbol encoding. Use **/NextDeveloper/Demos/Keyboard.app** to bind the desired key to symbol 0xA0 in your keymapping and you will be able to type the Euro currency symbol.

No Euro glyph support in OPENSTEP rulebooks
Apple reference # 2265773

PROBLEM:
The AppKit rulebooks did not support the Euro currency character.

RESOLUTION:
The rulebooks have been updated to provide support for the Euro currency symbol, U+20AC. The encoding tables in Foundation have also been updated to support this character. You will still need to obtain and install fonts which include the Euro character in order to generate the character itself.

NSDateFormatter interprets year "00" as "Current Year"
Apple reference # 2278598

PROBLEM:
NSCalendarDate would interpret year "0" or "00" as "current year", rather than "2000", which was inconsistent with the interpretation of two-digit years in UNIX and not Year 2000 compliant.

RESOLUTION:
NSCalendarDate now interprets "0" or "00" year values as "2000"

Date formatter handles two digit year inappropriately
Apple reference # 2290369

PROBLEM:
NSCalendarDate would treat any two-digit year as a 20th century year.

RESOLUTION:
NSCalendarDate now treats two-digit year values less than 30 as 21st century years.

adjtime() does not affect system time
Apple reference # 2231714

PROBLEM:
The adjtime() system function, intended to allow the synchronization of the system clock, actually had no effect. This would cause problems with network time synchronization under OPENSTEP for Mach.

RESOLUTION:
The adjtime() function now correctly adjusts the system clock.

System panic while writing disk label
Apple reference # 2279630

PROBLEM:

Writing a disk label would cause a kernel panic in some circumstances.

RESOLUTION:
The system has been modified to eliminate these kernel panics.

Sound input gain preferences behaves oddly
Apple reference # 2272986

PROBLEM:
In the OPENSTEP for Mach sound preferences panel, requests to set the right input channel gain on the sound input device would be ignored. This would produce strange behavior in the sound preferences panel input gain sliders.

RESOLUTION:
The sound preferences panel sliders now behave as expected.

Restrictive nbuf limit in kernel
Apple reference # 2296405

PROBLEM:
The OPENSTEP Mach kernel was previously restricted to use at most 255 buffers.

RESOLUTION:
This restriction has been removed. You can specify nbuf=xxx at the boot prompt or in the **System.config/Instance0.table** file to use any number of buffers. If no value is specified, the default is still limited to 255. **NOTE:** If you choose too large a value, your system may panic at boot time; however, as long as your system will boot, you will experience no instability as a result of a large nbuf value.

Euro glyph doesn't display correctly
Apple reference # 2298782

PROBLEM:
The NSTextView's **-insertText:** method would not handle mutable attributed strings correctly under OPENSTEP for Mach and Windows NT. This would result in display problems for certain characters, including the Euro currency symbol.

RESOLUTION:
This method now handles attributed strings as well as ordinary strings correctly.

Can't install OPENSTEP on partitions beginning after 4GB
Apple reference # 2265513

PROBLEM:
The **disk** command was not able to initialize an OPENSTEP for Mach partition beginning at a large offset on the drive, and would not correctly partition a large fdisk slice on EIDE drives.

RESOLUTION:
The 'disk' command can now initialize partitions at any offset.

mfks fails with a write error
Apple reference # 2284310
PROBLEM:
While building a new OPENSTEP for Mach filesystem, the 'mkfs' command would fail with a write error for some combinations of disk geometry and filesystem options.

RESOLUTION:
The **mfks** command will now lay out these filesystems correctly.

fdisk disk cylinder limit
Apple reference # 2305698

PROBLEM:

With some BIOS versions, the 'fdisk' command was unable to process disks with more than 2^10 cylinders.

RESOLUTION:
The limit has been increased to 2^16 cylinders.

Corrected in OPENSTEP 4.2 for Mach Patch 1

Four Digit Year Entry with /bin/date
Apple reference # : 2179467

PROBLEM:
Certain dates could not be input using the Unix /bin/date command which shipped with OPENSTEP 4.2.

RESOLUTION:
The /bin/date command now correctly handles 2-, 3-, and 4-digit years for dates in the valid Unix range (1 Jan 1970 - 31 Dec 2037). This patch allows four-digit year entry through /bin/date. In addition, input dates are now checked for validity and out-of-range dates are rejected.

New RCS Package
Apple reference # : 2249097

PROBLEM:
The version of RCS which shipped with OPENSTEP 4.2 did not handle dates after 1999 correctly in some commands.

RESOLUTION:
This patch installs RCS version 5.7, a much more recent version which does not experience this date problem. Please see the RCS documentation for a complete list of new and updated features in this release.

Hardware Clock Setting
Apple reference # : 2253935, 2258123

PROBLEM:
Previously, setting a date after 1999 with /bin/date or with the OPENSTEP Preferences application would cause an illegal value to be stored in the hardware clock of Intel and NeXT-branded Motorola hardware systems. As a result, some systems would show an incorrect year after reboot.

RESOLUTION:
With this patch, the hardware clock is now set correctly for dates after 1999.

Date handling in ftpd
Apple reference # : 2251927

PROBLEM:
The ftp daemon's MDTM command did not handle dates after 1999 correctly.

RESOLUTION:
The ftp daemon has been updated to handle these dates correctly.

tmac Macro Date Handling
Apple reference # : 2256331

PROBLEM:
Previously, default dates generated by the tmac macros used for troff and nroff typesetting were not correct for years after 1999.

RESOLUTION:
The various man, me, and ms macros now generate default dates after 1999 correctly.

Date reporting in atq
Apple reference # : 2258151

PROBLEM:
In OPENSTEP 4.2, the atq command displayed the job date incorrectly for jobs created with the at command after 1999.

RESOLUTION:
The atq command has been modified to correctly represent jobs scheduled from 1970 through 2037.

Job scheduling and execution with at and atrun

Apple reference # : 2263271

PROBLEM:
Under certain circumstances, atrun did not correctly handle jobs scheduled with at after 1999.

RESOLUTION:
The at and atrun commands have been modified to correctly and consistently handle the scheduling and execution of jobs regardless of date.

Date display in /usr/ucb/mail
Apple reference # : 2259253

PROBLEM:
In OPENSTEP 4.2, the Date: header of email messages written by /usr/lib/sendmail used a two-digit year in the creation time. This problem affected email created and read with the /bin/mail and /usr/ucb/mail programs.

RESOLUTION:
sendmail has been modified to write four-digit years in the date header.

ntpd Error Messaging
Apple reference # : 2260775

PROBLEM:
Under OPENSTEP 4.2, the error message returned when an excessive offset was encountered did not report the year correctly for years after 1999.

RESOLUTION:
This error message now reports the year correctly.

Sybase Adaptor Primary Key Generation Bug Workaround

This patch is now **obsolete**. Please see the WebObjects Current Patch List, **TIL article 70037**, forinformation on the most current patches for WebObjects and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.
This workaround solves the following problem that would occur under WebObjects 4.0. The problem has been corrected in the WebObjects 4.0.1 release. Apple recommends that all users of WebObjects 4.0 upgrade to WebObjects 4.0.1. If you are not sure what version of WebObjects you are using, please see **TIL article 70055**.

Sybase adaptor may generate duplicate primary keys for multiple application instances
Apple reference # 2299035
PROBLEM:
The Sybase adaptor uses a stored procedure called "eo_pk_for_table" to generate primary key values. Because this stored procedure does not run in a transaction, if two application instances request a primary key simultaneously, they could be assigned the same primary key.

RESOLUTION:
To prevent duplicate primary keys from being generated, you'll need to replace the definition for the "eo_pk_for_table" stored procedure, created in your database by EOModeler, with one that includes a transaction. The original definition will look like this:

```
create procedure eo_pk_for_table @tname varchar(32) as
begin
   declare @max int
   update eo_sequence_table set counter = counter + 1
      where table_name = @tname
   select counter from eo_sequence_table where table_name = @tname
end
```

Replace it with the corrected version below:

```
create procedure eo_pk_for_table @tname varchar(32) as
begin
 begin transaction
 update eo_sequence_table set counter = counter + 1 where table_name
= @tname
 select counter from eo_sequence_table where table_name = @tname
 commit
end
```

The exact commands you'll use to make the change will depend on the database access tool you're using. Assuming you're using isql at the command line, your session should look something like this:

```
1> drop procedure eo_pk_for_table
2> go
1> create procedure eo_pk_for_table @tname varchar(32) as
begin
 begin transaction
 update eo_sequence_table set counter = counter + 1 where table_name
= @tname
 select counter from eo_sequence_table where table_name = @tname
 commit
end
2> 3> 4> 5> 6> 7> 8> 9> go
```

Framework Headers And NT Compile Time

This document describes a problem WebObjects developers may encounter while developing applications using custom frameworks. This problem occurs on Windows NT for WebObjects 3.1, 3.5.1, 4.0, and 4.5.
This article has been archived and is no longer updated by Apple.
When building custom frameworks, many OPENSTEP and WebObjects developers working on the OPENSTEP for Mach platform use framework headers, combined with pre-compiled headers, to speed up the development cycle. A framework header is a header that include definitions for all classes in a framework. Together, these two elements can result in quicker compiles and eliminate the need to use separate #import or #include statements for each class your project uses.

Under Windows NT, pre-compiled headers are not an option. However, using unstripped framework headers for custom frameworks causes an increase in DLL size for each #import statement. This can increase compile time, slow down the debugger, and slow your development cycle substantially. Each header file which imports a framework will increase the size of the DLL. Therefore, unless you are using a framework with stripped headers, such as Apple's Foundation and WebObjects frameworks, always use a separate #import or @class statement to include only those files needed by a specific header. For example, instead of

```
#import <MyFramework/MyFramework.h> //import every header in the framework
```

use the faster:

```
#import <MyFramework/SomeClass.h> //a class need by this object

OPENSTEP 4.x Driver: VESA VBE Display

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.

NOTE: Apple Enterprise Software has suspended on-going development of new drivers for the NeXTSTEP and OPENSTEP product lines. Where possible, we will be updating current drivers for minor product revisions. These drivers will be made available in the TIL.

For a complete list of supported drivers for the OPENSTEP operating system, see the **OPENSTEP Driver Compatibility Guide**.
This article has been archived and is no longer updated by Apple.

Availability Information

This driver is included with and requires **OPENSTEP for Mach Patch 3**.

No updated versions of this driver are available

Driver Name / Installer .pkg: VBE20

Driver Type: Display

Driver Scope: Generic

Supported Components: N/A

General Overview notes:

The VBE Video Driver allows an OPENSTEP 4.2 system to use any VESA VBE 2.0 display adapter. Because of booter and kernel updates, use of the VBE driver requires installation of OPENSTEP for Mach Patch 2.

After this patch is installed, you can test your video card for compatibility with this driver by using the updated booter. At your system boot prompt, specify "VBE Check"=Yes. You will recieve either a list of supported VBE modes, or a message indicating that you cannot use the VBE driver. You can also create a boot floppy on patched system and use it to test for VESA compatibility before installing OPENSTEP on the system.

Display Driver Details

Display Modes:

The list of supported display modes will vary depending on the video hardware manufacturer's VESA VBE implementation.

Troubleshooting

Note: The boot graphics may hide error messages. If boot graphics are turned on and you are experiencing problems, reboot the system and specify "Boot Graphics"=No at the boot prompt. This may allow you to see additional error messages.

Problem: The system prints the following error, then boots using VGA:
VESA not available.
Diagnosis: This message indicates that the video card does not support VESA VBE 2.0. You will not be able to use the VBE driver with this card.

Problem: The system boots in VGA mode, and the VBE driver prints the following:
Skipping framebuffer initialization (card not in VBE mode).
Diagnosis: This message indicates that the booter did not leave the video card in a VBE mode. This message will only occur if you are booting from an alternate boot device, such as a floppy disk.
Suggestion: Specify Query=Yes at the boot prompt to verify that your boot device is using the updated booter. (The old booter will ignore this option, while the new booter will prompt before loading each driver.) Additionally, specify "Boot Graphics"=No to prevent the boot graphics from hiding booter error messages.

Problem: I've installed the VBE display driver, but there are no display modes listed in Configure.app.
Diagnosis: The list of display modes will be empty if the system has not been rebooted since OPENSTEP Patch 2 was installed, or if your video card does not provide the required VESA support.
Suggestion: Specify Query=Yes at the boot prompt to verify that your video card supports VESA.

Problem: The booter loads the drivers, the screen clears, and the system restarts.
Diagnosis: You may be trying to use a video mode which is incompatible with OpenStep. Known incompatible modes are detected and filtered out, but the VBE specification allows manufacturers to define their own video modes. It is possible that a mode for your particular card was not recognized as incompatible.
Suggestion: The "VBE Check"=Yes boot option will give you a list of supported video modes. Try using the "VBE Mode"=xxx boot option to boot with a different mode. (Remember to run Configure.app to permanently update the system's configuration.) If this fails you may not be able to

use the VBE driver with this display card. Specify Query=Yes at the boot prompt and do not load the VBE display driver. The system will fall back to using VGA and you should be able to boot and restore the system to a usable configuration.

Problem: The modes list in Configure.app all show a 0Hz refresh.
Diagnosis: Under VBE 2.0 the refresh rate is determined by the video card manufacturer, and there is no VBE interface to allow the software to determine what value is being used. This is why the 0Hz value appears in Configure.app. This is not a problem. (Some manufacturers supply utilities for configuring VESA mode characteristics like refresh rate and interlace.)

Driver Version Notes

4.00 - First version; released in OPENSTEP 4.2 Patch 2.

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

OPENSTEP Driver Compatibility Guide

This document describes in general terms the types of PC-compatible hardware supported by OPENSTEP for Mach Release 4.x for Intel Processors. This document also provides lists of specific drivers available for OPENSTEP. For more detail on a driver, click on the driver name.

NOTE: Apple Enterprise Software has suspended on-going development of new drivers for the NeXTSTEP and OPENSTEP product lines. Where possible, we will be updating current drivers for minor product revisions. These drivers will be made available in the TIL.

If you have specific requirements for drivers for hardware not currently supported, contact your AES sales representative for a quote for custom development work.

OVERVIEW

This guide is divided into six sections:

General System Requirements

Display Options

Networking Options

SCSI Options

Sound Options

System Options

GENERAL SYSTEM REQUIREMENTS

CPU
486 or Pentium family-based PC compatible computer. OPENSTEP for Mach requires a floating-point coprocessor. For information on OPENSTEP support for non-Intel CPUs, see **TIL article 72566**.

EXPANSION BUS

ISA, EISA, VL-Bus or PCI expansion bus.

AVAILABLE HARD DISK SPACE

OPENSTEP for Mach supports multiple partitioned hard disks, allowing the user to install and boot several operating systems from the same local hard disk. Larger local disks are recommended for stand-alone systems or for systems with a local non-OPENSTEP for Mach partition.

- **User Environment**:120 MB partition minimum, 200 MB recommended for stand-alone systems.
- **User + Developer Environments**: 330 MB partition minimum, 400 MB recommended.

RAM REQUIREMENTS

RAM requirements vary depending upon your selection of graphics adapter and imaging model.

- 32-bit color: 24 MB RAM Minimum, 32 MB RAM Recommended
- 16-bit color: 16 MB RAM Minimum, 24 MB RAM Recommended
- 8-bit color/grayscale: 12 MB RAM Minimum, 16 MB RAM Recommended
- 2-bit grayscale: 8 MB RAM Minimum, 12 MB RAM Recommended

GRAPHICS ADAPTERS

See the "Display Options" section in this guide for details on graphics support.

DISK INTERFACES

IDE and several SCSI hard disk interfaces are supported. See later sections of this guide for details.

POINTING DEVICES

See the "System Options" and "Other Options" sectiosn in this guide for details on pointing device support.

PRINTERS

Any PostScript printer connected via a serial port, parallel port or network including the NeXT Color Printer (connected via a SCSI port). Apple Computer recommends color PostScript printers with PostScript Level II for proper color support.

NETWORKING

Several Ethernet and Token Ring networking adapters are supported. A networking adapter is optional. See below for details.

SOUND
OPENSTEP for Mach can support certain PC sound cards for both playback and recording. A sound card is optional. See below for details.

OPENSTEP 4.2 for Mach Developer Patch 2 Overview

This patch is now obsolete. Please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.
This patch is obsolete; please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework.

Installing OPENSTEP 4.2 for Mach Developer Patch 2

1. Download the Mach version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/

patches/4.2Mach_Dev_Patch2.compressed
```

2. Uncompress the Mach package file. Your web browser or FTP client may perform this step for you.

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Double-click on the 4.2_Mach_Developer_Patch2.pkg file. Make sure that no OPENSTEP applications are running before you do this step.

5. Click the Install button in the Installer package window. An Install Package panel will open.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, **click OK** to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

NOTE: Some versions of OmniWeb for OPENSTEP Mach add a .Z extension to downloaded files, causing uncompression errors. To correct this problem, find the downloaded file in the file system and remove the .Z extension before uncompressing it.

Problems Fixed

Corrected in OPENSTEP 4.2 for Mach Patch 2

IB palette has poor default date formatter
Apple reference # 2296018

PROBLEM:
By default, NSDateFormatters dragged in from the Interface Builder palette had a two-digit year format. The default should be a four-digit year format to encourage sound coding practices.

RESOLUTION:
The default has been changed to a four-digit year format.

OPENSTEP 4.2 for Mach: Updated ProfileLibraries

This document contains installation and download information for the most recent versions of Apple's ProfileLibraries for OPENSTEP 4.2.

The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read this document if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.

About The Libraries

Apple's ProfileLibraries and the **gprof** profiling tool allow developers to run certain performance tests on their OPENSTEP applications. The gprof tool depends on special versions of the AppKit and Foundation libraries, and it is important that these libraries match the non-profiler libraries used for development and deployment. For this reason, Apple has prepared updated ProfileLibraries which include all Foundation and AppKit changes included in **OPENSTEP 4.2 for Mach Patch 3**. If you have this patch installed, installing these libraries will allow you to take advantage of these framework changes while using gprof. Non-developers and develoepers not using gprof for performance testing do not need to download this package.

Installing the updated ProfileLibraries

1. Download the Mach version of the libraries from Apple's FTP site at ftp.info.apple.com. The file is located at:

`ftp://ftp.info.apple.com//Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/patches/4.2Mach_PLib_Patch2.compressed`

2. Uncompress the Mach package file. Your web browser or FTP client may perform this step for you.

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Double-click on the 4.2_Mach_ProfileLibs_Patch2.pkg file. Make sure that no OPENSTEP applications are running before you do this step.

5. Click the Install button in the Installer package window. An Install Package panel will open.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, **click OK** to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

NOTE: Some versions of OmniWeb for OPENSTEP Mach add a .Z extension to downloaded files, causing uncompression errors. To correct this problem, find the downloaded file in the file system and remove the .Z extension before uncompressing it.

OPENSTEP 4.2 Enterprise Patch 2 for Windows NT Overview

This patch is now obsolete. Please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.

About This Patch

This patch is obsolete; please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This patch contained a number of important bug fixes, including corrections for some Year 2000 problems and improved support for the Euro currency symbol.

Installing OPENSTEP 4.2 Enterprise Patch 2 on Windows NT 4.0

1. Download the Windows NT version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/

patches/4.2NT_Patch2.TAR.gz
```

Also **download** the installer script, "patcher.nt.sh" from:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/

patches/patcher.nt.sh
```

2. Log in as a user with Administrator privileges.

3. Open a Bourne shell. The Bourne shell should be available from your Start menu, under the WebObjects program group, or under your Apple root directory at Demos\\sh.exe.

4. Change to the directory containing the patch and the patch installer, "patcher.nt.sh".

5. Type the following at the shell prompt (make sure that there are no EOF applications running first):

```
patcher.nt.sh -install 4.2NT_Patch2.TAR.gz
```

For more information on using the patcher.nt.sh program, type the following at the command prompt:

```
patcher.nt.sh -help
```

6. Reboot your Windows NT system

No Euro glyph support in OPENSTEP rulebooks
Apple reference # 2265773

PROBLEM:
The AppKit rulebooks did not support the Euro currency character.

RESOLUTION:
The AppKit rulebooks have been updated to provide support for the Euro currency symbol, U+20AC. The encoding tables in Foundation have also been updated to support this character. You will still need to obtain and install fonts which include the Euro character in order to generate the character itself.

NSDateFormatter interprets year "00" as "Current Year"
Apple reference # 2278598

PROBLEM:
NSCalendarDate would interpret year "0" or "00" as "current year", rather than "2000", which was inconsistent with the interpretation of two-digit years in UNIX and not Year 2000 compliant.

RESOLUTION:

NSCalendarDate now interprets "0" or "00" year values as "2000"

Date formatter handles two digit year inappropriately
Apple reference # 2290369

PROBLEM:
NSCalendarDate would treat any two-digit year as a 20th century year.

RESOLUTION:
NSCalendarDate now treats two-digit year values less than 30 as 21st century years.

Euro glyph doesn't display correctly
Apple reference # 2298782

PROBLEM:
The NSTextView's **-insertText:** method would not handle mutable attributed strings correctly under OPENSTEP for Mach and Windows NT. This would result in display problems for certain characters, including the Euro currency symbol.

RESOLUTION:
This method now handles attributed strings as well as ordinary strings correctly.

OPENSTEP Current Patch List

This document discusses the current patches available for Apple's OPENSTEP operating system and for Enterprise Objects Framework. Follow the links in this article for detailed information on each patch.

This article has been archived and is no longer updated by Apple.

OPENSTEP 4.2 for Mach

All OPENSTEP 4.2 for Mach users should install the following patch:

- **OPENSTEP 4.2 Patch 4**--This patch set includes fixes that address the Year 2000 compliance issue (century rollover). All users of OPENSTEP 4.2 should install this patch set. OPENSTEP 4.2 Patch 4 supercedes all previous OPENSTEP general system patches. If you have already installed an OPENSTEP patch on your system, you can install Patch 4 over your existing installation. You do not need to install any other OPENSTEP patches before installing this one.

There are several additional patches you may wish to install, depending on your needs:

- **Updated ProfileLibraries for OPENSTEP 4.2 for Mach**--This patch should only be installed by developers who use the **gprof** utility for performance testing.
- **Sybase DBKit Adaptor Patch**--This patch should be installed **only** if you need to use DBKit-based legacy applications to access a Sybase database under OPENSTEP 4.2 for Mach

OPENSTEP Enterprise 4.2 for Windows NT

All OPENSTEP 4.2 for Windows NT users should install the following patch:

- **OPENSTEP 4.2 Patch 4**--This patch set includes fixes that address the Year 2000 compliance issue (century rollover). All users of OPENSTEP 4.2 should install this patch set. OPENSTEP 4.2 Patch 4 supercedes all previous OPENSTEP general system patches. If you have already installed an OPENSTEP patch on your system, you can install Patch 4 over your existing installation. You do not need to install any other OPENSTEP patches before installing this one.

OPENSTEP Enterprise 4.2 for Solaris and HP-UX

All OPENSTEP 4.2 for Solaris and HP-UX users should install the following patch:

- **OPENSTEP 4.2 Patch 4**--This patch set includes fixes that address the Year 2000 compliance issue (century rollover). All users of OPENSTEP 4.2 should install this patch set. OPENSTEP 4.2 Patch 4 supercedes all previous OPENSTEP general system patches. If you have already installed an OPENSTEP patch on your system, you can install Patch 4 over your existing installation. You do not need to install any other OPENSTEP patches before installing this one.

OPENSTEP 4.0 and 4.1 for Mach

There are two patches available to users of OPENSTEP 4.1 for Mach:

- **NeXTSTEP and OPENSTEP Time Zone Patch**--This patch corrects an issue with European daylight savings time under OPENSTEP 4.0 and 4.1
- **Sybase DBKit Adaptor Patch**--This patch hould be installed **only** if you need to use DBKit-based legacy applications to access a Sybase database under OPENSTEP 4.0 or OPENSTEP 4.1 for Mach

OPENSTEP Enterprise 4.0 and 4.1 for Windows NT, Solaris, and HP-UX

There are no patches currently available for OPENSTEP Enterprise 4.0 or 4.1.

Enterprise Objects Framework 2.1

There are no patches currently available for users of EOF 2.1, but you should read the following article if you use the examples provided with EOF.

- **Correcting Century Issues in the EOF Examples**--Apple is not aware of any century issues with Enterprise Objects Framework version 2.1 which would affect development or deployment of EOF applications. However, two scripts which install exaple data on Oracle for the Enterprise Objects Examples use a two-digit year format, which is not consistent with Apple's date-handling practice. This article provides instructions on how to change the EOF examples to avoid this issue.

Enterprise Objects Framework 2.0

There are several patches available for current users of EOF 2.0:

- EOF 2.0 Adaptor patches for the **ODBC**, **Oracle**, and **Informix** adaptors
- A **workaround** for a issue with multiple BLOBs under EOF 2.0
- **Sybase client libraries** for EOF 2.0

Enterprise Objects Framework 1.2

There are no patches currently available for users of EOF 1.2, but you should read the following article if you use the examples provided with EOF.

- **Correcting Century Issues in the EOF Examples**--Apple is not aware of any century issues with Enterprise Objects Framework version 1.2 which would affect development or deployment of EOF applications. However, two scripts which install exaple data on Oracle for the Enterprise Objects Examples use a two-digit year format, which is not consistent with Apple's date-handling practice. Linking Windows NT DLL‘s into OPENSTEP 4.1 applications

This document explains how to link a DLL into a compiled OPENSTEP Enterprise 4.1 application on Windows NT. The procedure also applies to WebObjects version 3.0 on Windows NT.
This article has been archived and is no longer updated by Apple.
In most versions of OPENSTEP and WebObjects, linking a .dll into your project is simply a case of dragging and dropping the library's .lib file into the Libraries folder of your Project Builder project, then using the Inspector to add your library's header files to the project's search order.

However, there was a bug in the version of ProjectBuilder that shipped with OPENSTEP 4.1 and WebObjects 3.0. If you are using either of these versions, do not add the library with the ProjectBuilder browser. Instead, add the library name to the makefile directly, in the OTHER_LIBS keyword. Then put a copy of the .lib file in your application directory under the obj-i386-nextpdo-winnt3.5-opt directory. You will also need to add this value to the OTHER_LDFLAGS keyword:

```
OTHER_LDFLAGS = $(LIBRARY_PATHS)
```

These problems have been fixed in OPENSTEP 4.2 and WebObjects 3.1.

NeXTSTEP Current Patch List

This document discusses the current patches available for Apple's NeXTSTEP operating system and for NeXTSTEP versions of the Enterprise Objects Framework. Follow the links in this article for detailed information on each patch.

This article has been archived and is no longer updated by Apple.

NeXTSTEP 3.3

All NeXTSTEP 3.3 users should install the following patch:

- **NEXTSTEP 3.3 Patch 3**--This patch contains general fixes for the NeXTSTEP operating system, including date handling issues related to the year 2000.

There are several additional patches you may wish to install, depending on your needs:

- **NeXTSTEP and OPENSTEP Time Zone Patch**--This patch corrects an issue with European daylight saving time under NeXTSTEP 3.3
- **NeXTSTEP NT Printer Patch**--This patch corrects an issue with printing to Windows NT 3.1 printers from NeXTSTEP.

NeXTSTEP versions previous to 3.3

There are several patches now available for users of NeXTSTEP versions previous to NeXTSTEP 3.3:

- **NeXTSTEP NT Printer Patch**--This patch corrects an issue with printing to Windows NT 3.1 printers from NeXTSTEP.
- **NeXTSTEP 3.2 HP-PA Precompiled Header Patch**--This patch fixes an incompatibility issue with the PA-RISC versions of NeXTSTEP 3.2.
- **NeXTSTEP 3.1/3.2 Sendmail Patch**--This patch fixes some security issues with the **sendmail** utility.
- **NeXTSTEP 3.2 DOS Filesystem Patch**--This patch corrects some filesystem interoperablity issues.
- **NeXTSTEP 3.2 libg++ Patch**--This patch installs the libg++ library on NeXTSTEP 3.2 systems.
- **NeXTSTEP 3.2 /etc/restore Patch**--This patch installs /etc/restore Update 1.
- **NeXTSTEP 3.2 DBKit Oracle Adaptor Patch**--This patch should be installed only by DBKit users.
- **NeXTSTEP 3.2 libMallocDebug Patch**--This patch should be installed by NeXTSTEP developers who use the debugging features of **malloc**.

Enterprise Objects Framework 1.1

There are no patches currently available for users of EOF 1.1, but you should read the following article if you use the examples provided with EOF.

- **Correcting Century Issues in the EOF Examples**--Apple is not aware of any century issues with Enterprise Objects Framework version 1.1 which would affect development or deployment of EOF applications. However, two scripts which install exaple data on Oracle for the Enterprise Objects Examples use a two-digit year format, which is not consistent with Apple's current date-handling practice. This article provides instructions on how to change the EOF examples to avoid this issue.

Enterprise Objects Framework 1.0

There are no patches currently available for users of EOF 1.0.

NeXTSTEP Driver Compatibility Guide

This document describes in general terms the types of PC-compatible hardware supported by NeXTSTEP Release 3.3. This document also provides lists of specific drivers available for NeXTSTEP. For more detail on a driver, click on the driver name.

NOTE: Apple Enterprise Software has suspended on-going development of new drivers for the NeXTSTEP and OPENSTEP product lines. Where possible, we will be updating current drivers for minor product revisions. These drivers will be made available in the TIL.

If you have specific requirements for drivers for hardware not currently supported, contact your AES sales representative for a quote for custom development work.

OVERVIEW

This guide is divided into six sections:

General System Requirements

Display Options

Networking Options

SCSI Options

Sound Options

System Options

GENERAL SYSTEM REQUIREMENTS

CPU

486, Pentium, or Pentium, Pro based PC compatible computer. NeXTSTEP requires a floating-point coprocessor. Systems using processors without a built-in floating-point coprocessor require an add-on floating-point coprocessor, or upgrade to a 486, Pentium or Pentium Pro with built-in floating-point support.

EXPANSION BUS

ISA, EISA, VL-Bus or PCI expansion bus.

AVAILABLE HARD DISK SPACE

NEXTSTEP supports multiple partitioned hard disks, allowing the user to install and boot several operating systems from the same local hard disk. Larger local disks are recommended for stand-alone systems or for systems with a local non-NEXTSTEP partition.

User Environment:120 MB partition minimum, 200 MB recommended for stand-alone systems.

User + Developer: Environments: 330 MB partition minimum, 400 MB recommended.

RAM REQUIREMENTS

RAM requirements vary depending upon your selection of graphics adapter and imaging model.

32-bit color: 24 MB RAM Minimum, 32 MB RAM Recommended

16-bit color: 16 MB RAM Minimum, 24 MB RAM Recommended

8-bit color/grayscale: 12 MB RAM Minimum, 16 MB RAM Recommended

2-bit grayscale: 8 MB RAM Minimum, 12 MB RAM Recommended

GRAPHICS ADAPTERS

See the "Display Options" section in this guide for details on graphics support.

DISK INTERFACES

IDE and several SCSI hard disk interfaces are supported.

POINTING DEVICES

Microsoft(tm) and Logitech(tm) compatible PS/2(tm) and serial mice. Logitech bus mouse.

PRINTERS

Any PostScript printer connected via a serial port, parallel port or network including the NeXT Color Printer (connected via a SCSI port). Apple Computer recommends color PostScript printers with PostScript Level II for proper color support.

NETWORKING

Several Ethernet and Token Ring networking adapters are supported. A networking adapter is optional.

SOUND

NEXTSTEP can support certain PC sound cards for both playback and recording. A sound card is optional.

Communications ToolBox: 3270 Tools Information

Are there any plans for a 3270 connection tool for the Communications Toolbox?

This article has been archived and is no longer updated by Apple.
Advanced Software Concepts has acs3270, a terminal tool to allow access to IBM computers using TCP/IP. It will also support AS/400 connections. They are planning to support DEC SNA/Gateways within the near future. Educational institutions get a special discount. Site licensing is available upon request. Special feature for those very large accounts: a special installer that lets the system administrator freeze some or all settings.

For contact information, search the Technical Info library under "Advanced Software Concepts."

WebObjects 4: Public and Private WebObjects.conf Files

This article discusses the interaction between the public and private WebObjects.conf files in WebObjects 4.0.
This article has been archived and is no longer updated by Apple.

About the WebObjects.conf Files

WebObjects.conf is a file that tells your WebObjects adaptor where to find application instances. A standard WebObjects deployment contains two WebObjects.conf files.

- The **public** WebObjects.conf file is located in the **Configuration** directory inside your Apple library directory, usually **/opt/Apple/Library**, **$NEXT_ROOT/Library**, or **System/Library**. This file is created by the user and by Monitor.app. It is read by the adaptor, but not by Monitor.app. Monitor.app creates the file by using information from the Monitor.conf file.
- The **private** WebObjects.conf file is located in your web server's **/tmp** directory on Unix, or **\\temp** directory on Windows NT. This file is updated by WebObjects applications and read by the WebObjects adaptor. It is not directly accessed by Monitor.app.

The Public WebObjects.conf file

The public WebObjects.conf file is created by the user, either manually with a text editor or through Monitor. It contains a one-line entry for every instance of every application that is running. For example, if you had three instances of HelloWorld running, the file would look something like this:

```
HelloWorld:1@lothrup 2001
HelloWorld:2@lothrup 2002
HelloWorld:3@lothrup 2003
```

The format for each entry is:

```
Application_Name:Instance_Number@Application_Server_Name Port_Number
```

The instance numbers are unique to each application. Monitor will write an entry to this file **only** after it has successfully started an instance.

The Private WebObjects.conf File

The private WebObjects.conf file is created by a WebObjects application. The private file looks a lot like the public file:

```
Monitor:-1@localhost 5000
HelloWorld:-1@localhost 5601
GinIntTest:-1@localhost 51747
```

However, even if you have multiple instances of a given application on different port numbers, you will only see one entry per application in the private WebObjects.conf file. Instead of adding a second entry, the WOApplication will overwrite a previous instance's entry. This is to facilitate rapid deployment and testing.

The WebObjects.conf Files In a Deployment

When and how often the WebObjects.conf file is read depends on your adaptor configuration. Because it does not store state, the CGI adaptor checks the file once per transaction. Other adaptors can be configured at compile time. Two variables are set in the **config.h** file that is part of the adaptor source distribution:

```
#define READ_CONF_ONCE 0
#define CONF_STAT_INTERVAL 10
```

If **READ_CONF_ONCE** is set to a value greater than zero, the WebObjects.conf files are read once at startup and then never consulted again. The **CONF_STAT_INTERVAL** value determines how often, in seconds, the public WebObjects.conf file is **stat()**'ed. If the time stamp of this file has changed, the file is reloaded.

If the adaptor receives a request for an application that is not in the public conf file, it will then drop down to look at the private conf file. If the adaptor can't find the application in either place, then it will pop out a "Application can not be found" error.

OPENSTEP 4.2 Mach: The Euro Currency Symbol

This article explains how to use the Euro currency symbol with the OPENSTEP for Mach operating system, version 4.2.
This article has been archived and is no longer updated by Apple.

OPENSTEP and the Euro

Because Apple's OPENSTEP 4.2 for Mach operating system was released before the Euro symbol was created, the built-in fonts and key mappings do not take the Euro into account. Many third-party fonts are available which include the Euro character. These fonts fall into two categories:

- Fonts which **map every keystroke to the Euro character**
- Fonts which **include the Euro character as part of a standard character set**

Using a Font with Only the Euro Character

A set of fonts which map every character to the Euro symbol is available free from Adobe. Because every character in this font will draw a Euro glyph, no special keyboard mapping or other configuration is required. To install:

- Download the fonts from http://www.adobe.com/type/eurofont.html
- Use a third-party utility to convert the font to OPENSTEP format
- Follow the standard procedure to install the new font on your OPENSTEP system

After you've converted and installed the fonts, simply type any character and change it to the appropriate Euro font. Bear in mind that the Euro character will not display on systems or print on printers which do not have the appropriate Euro font installed.

Using a Font Which Includes The Euro Character

Many standard PostScript fonts are available which include the Euro glyph in their standard character set. To use one of these fonts under OPENSTEP:

If you haven't already, install OPENSTEP 4.2 for Mach Patch 2 on your system

- Convert the font to OPENSTEP format if necessary
- Follow the standard procedure to install the new font on your OPENSTEP system
- Choose a key you wish to represent the Euro character
- Use /NextDeveloper/Demos/Keyboard.app to bind the desired key to symbol 0xA0 in your keymapping
- Save your new key mapping to ~/Library/Keyboards or /LocalLibrary/Keyboards

Applications not based on the OPENSTEP AppKit, such as Mail, Edit, and Workspace, won't be able to display the Euro character. However, you will now be able to use the Euro character in all AppKit-based applications. You can also create strings containing the Euro character programmatically, using NSString's initWithCharacters: method. The Euro currency symbol has a Unicode value of 0x20ac.

WebObjects Year 2000 Technical Tips

This article discusses ways developers can avoid causing Year 2000 problems in their code, including some issues relating specifically to Apple's OPENSTEP and WebObjects frameworks and API's. This article does **not** discuss the Year 2000 compliance status of any Apple product; for Y2K compliance information, see the Apple Year 2000 main page at http://www.apple.com/about/year2000 .

The following are tips for programmers; we hope they will help you avoid some common problems in your code, and identify problems in your legacy code for remediation.
This article has been archived and is no longer updated by Apple.

Working with Dates in WebObjects

A detailed overview of date handling in WebObjects is now available for **download in PDF format**.

Use Consistent Date Handling

Consistency in date hanlding makes maintaining and fixing date-handling code easier. Apple recommends that you always use the Foundation date and time API's when you need to write date-handling code for OPENSTEP or WebObjects.

Don't Divide By an NSTimeInterval Value

Dates are represented in the Foundation framework with **NSDate** and **NSCalendarDate** objects and **NSTimeInterval** values. An **NSTimeInterval** object is essentially a C-language double (**NSTimeInterval** can represent intervals of approximately 10,000 years with sub-millisecond accuracy). **NSDate** and **NSCalendarDate** store the date that they represent with an **NSTimeInterval** which represents the time delta in seconds from the Foundation reference date (00:00:00 Greenwich Mean Time January 1, 2000). Since the internal time representation will transition across zero at the reference date, there will be a brief instant (on the order of microseconds in length) during which an **NSDate** object created to represent the current time will have an **NSTimeInterval** of zero. An **NSTimeInterval** of zero has no special significance to **NSDate** or **NSCalendarDate**, but applications that use the **NSTimeInterval** of a date object in division should protect against division by zero. This is unlikely to occur in real-world applications.

Avoid Two-Digit Date Formats

Always use four-digit years when formatting dates for input or output; a four-digit year is the **only** unambiguous way to refer to any date. The Foundation framework's date formatting objects may interpret two-digit year values in unexpected ways, and using the two-digit "%y" format allows no way for a user to present a date unambiguously and may cause additional problems; for example, typing "2004" into a two-digit year formatted field result in a value of "20" being used and "04" being truncated. Instead, use the four-digit "%Y" year format.

OPENSTEP 4.2 for Mach Patch 3

This patch is now obsolete. Please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.

About This Patch

This patch is obsolete; please see the OPENSTEP Current Patch List, **TIL article 70033**, for information on the most current patches for OPENSTEP and Enterprise Objects Framework. This patch was an updated version of OPENSTEP 4.2 Patch 2. This patch included all of the bug fixes and features from that patch, including corrections for some Year 2000 issues, improved support for the Euro currency symbol, support for large hard drives on OPENSTEP systems, and a VESA VBE driver. In addition, this patch corrected some issues with file permissions on OPENSTEP for Mach systems. For more information on these topics, please see the appropriate section of this document.

Installing OPENSTEP 4.2 for Mach Patch 3

1. **Download** the Mach version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/

patches/4.2Mach_Patch3.pkg.tar
```

2. Uncompress the Mach package file. Your web browser or FTP client may perform this step for you.

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Double-click on the 4.2_Mach_Patch3.pkg file. Make sure that no OPENSTEP applications are running before you do this step.

5. Click the Install button in the Installer package window. An Install Package panel will open.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, **click OK** to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

New Features

New in OPENSTEP 4.2 for Mach Patch 2

VBE VESA Driver

This patch installs a VBE video driver. This driver allows an OPENSTEP 4.2 system to use any display adapter which conforms to version 2.0 of the VESA BIOS extension standard. Use of the VBE driver requires updating the kernel and the booter. The updated kernel and booter are also compatible with all other video drivers, and both are included in this patch. For more information, see the VESA VBE OPENSTEP Driver Overview, **TIL article 70026**.

New Booter Features

The new booter included in this patch includes two new features:

1. If you are using the new VESA VBE driver, you can **specify a VBE video mode at boot time**. Specify **"VBE Check"=Yes** at the boot prompt to get a list of available VBE video modes. Then use **"VBE Mode"=xxx** to specify the mode number you want to use. The mode number is the three-digit number listed before each mode. For example, if one of the listed video modes was:

257=640x480x256

you would type **"VBE Mode"=257** at the booter prompt to boot with 640x480, 256-color VESA graphics.

2. The new booter allows you to **step through your boot drivers**, choosing which to load and which to skip. Specify **Query=Yes** at the boot prompt, and the booter will prompt before loading each boot driver.

Issues Fixed

Corrected in OPENSTEP 4.2 for Mach Patch 3

Permissions issues in system files
Apple reference # 2318668

ISSUE:
Certain system files included in OPENSTEP 4.2 Patch 2 had incorrect permissions settings. This caused issues with sendmail and some other system resources.

RESOLUTION:
These permissions have been corrected in this patch.

Corrected in OPENSTEP 4.2 for Mach Patch 2

No Euro symbol support in OPENSTEP
Apple reference # 2265776

ISSUE:
OPENSTEP 4.2 for Mach did not include Euro currency symbol support.

RESOLUTION:
Support was added for the Euro currency symbol. Typing a Euro currency symbol character will require a modified keyboard keymapping. The currency character is encoded as symbol 0xA0 in the keyboard symbol encoding. Use **/NextDeveloper/Demos/Keyboard.app** to bind the desired key to symbol 0xA0 in your keymapping and you will be able to type the Euro currency symbol.

No Euro glyph support in OPENSTEP rulebooks
Apple reference # 2265773

ISSUE:
The AppKit rulebooks did not support the Euro currency character.

RESOLUTION:
The rulebooks have been updated to provide support for the Euro currency symbol, U+20AC. The encoding tables in Foundation have also been updated to support this character. You will still need to obtain and install fonts which include the Euro character in order to generate the character itself.

NSDateFormatter interprets year "00" as "Current Year"
Apple reference # 2278598

ISSUE:
NSCalendarDate would interpret year "0" or "00" as "current year", rather than "2000", which was inconsistent with the interpretation of two-digit years in UNIX and not Year 2000 compliant.

RESOLUTION:
NSCalendarDate now interprets "0" or "00" year values as "2000"

Date formatter handles two digit year inappropriately
Apple reference # 2290369

ISSUE:
NSCalendarDate would treat any two-digit year as a 20th century year.

RESOLUTION:
NSCalendarDate now treats two-digit year values less than 30 as 21st century years.

adjtime() does not affect system time
Apple reference # 2231714

ISSUE:
The adjtime() system function, intended to allow the synchronization of the system clock, actually had no effect. This would cause issues with network time synchronization under OPENSTEP for Mach.

RESOLUTION:
The adjtime() function now correctly adjusts the system clock.

System panic while writing disk label
Apple reference # 2279630

ISSUE:
Writing a disk label would cause a kernel panic in some circumstances.

RESOLUTION:
The system has been modified to eliminate these kernel panics.

Sound input gain preferences behaves oddly
Apple reference # 2272986

ISSUE:
In the OPENSTEP for Mach sound preferences panel, requests to set the right input channel gain on the sound input device would be ignored. This would produce strange behavior in the sound preferences panel input gain sliders.

RESOLUTION:
The sound preferences panel sliders now behave as expected.

Restrictive nbuf limit in kernel
Apple reference # 2296405

ISSUE:
The OPENSTEP Mach kernel was previously restricted to use at most 255 buffers.

RESOLUTION:
This restriction has been removed. You can specify nbuf=xxx at the boot prompt or in the **System.config/Instance0.table** file to use any number of buffers. If no value is specified, the default is still limited to 255. **NOTE:** If you choose too large a value, your system may panic at boot time; however, as long as your system will boot, you will experience no instability as a result of a large nbuf value.

Euro glyph doesn't display correctly
Apple reference # 2298782

ISSUE:
The NSTextView's **-insertText:** method would not handle mutable attributed strings correctly under OPENSTEP for Mach and Windows NT. This would result in display issues for certain characters, including the Euro currency symbol.

RESOLUTION:
This method now handles attributed strings as well as ordinary strings correctly.

Can't install OPENSTEP on partitions beginning after 4GB
Apple reference # 2265513

ISSUE:
The **disk** command was not able to initialize an OPENSTEP for Mach partition beginning at a large offset on the drive, and would not correctly partition a large fdisk slice on EIDE drives.

RESOLUTION:
The 'disk' command can now initialize partitions at any offset.

mfks fails with a write error

Apple reference # 2284310
ISSUE:
While building a new OPENSTEP for Mach filesystem, the 'mkfs' command would fail with a write error for some combinations of disk geometry and filesystem options.

RESOLUTION:
The **mfks** command will now lay out these filesystems correctly.

fdisk disk cylinder limit
Apple reference # 2305698

ISSUE:
With some BIOS versions, the 'fdisk' command was unable to process disks with more than 2^10 cylinders.

RESOLUTION:
The limit has been increased to 2^16 cylinders.

Corrected in OPENSTEP 4.2 for Mach Patch 1

Four Digit Year Entry with /bin/date
Apple reference # : 2179467

ISSUE:
Certain dates could not be input using the Unix /bin/date command which shipped with OPENSTEP 4.2.

RESOLUTION:
The /bin/date command now correctly handles 2-, 3-, and 4-digit years for dates in the valid Unix range (1 Jan 1970 - 31 Dec 2037). This patch allows four-digit year entry through /bin/date. In addition, input dates are now checked for validity and out-of-range dates are rejected.

New RCS Package
Apple reference # : 2249097

ISSUE:
The version of RCS which shipped with OPENSTEP 4.2 did not handle dates after 1999 correctly in some commands.

RESOLUTION:
This patch installs RCS version 5.7, a much more recent version which does not experience this date issue. Please see the RCS documentation for a complete list of new and updated features in this release.

Hardware Clock Setting
Apple reference # : 2253935, 2258123

ISSUE:
Previously, setting a date after 1999 with /bin/date or with the OPENSTEP Preferences application would cause an illegal value to be stored in the hardware clock of Intel and NeXT-branded Motorola hardware systems. As a result, some systems would show an incorrect year after reboot.

RESOLUTION:
With this patch, the hardware clock is now set correctly for dates after 1999.

Date handling in ftpd
Apple reference # : 2251927

ISSUE:
The ftp daemon's MDTM command did not handle dates after 1999 correctly.

RESOLUTION:
The ftp daemon has been updated to handle these dates correctly.

tmac Macro Date Handling
Apple reference # : 2256331

ISSUE:
Previously, default dates generated by the tmac macros used for troff and nroff typesetting were not correct for years after 1999.

RESOLUTION:
The various man, me, and ms macros now generate default dates after 1999 correctly.

Date reporting in atq
Apple reference # : 2258151

ISSUE:
In OPENSTEP 4.2, the atq command displayed the job date incorrectly for jobs created with the at command after 1999.

RESOLUTION:
The atq command has been modified to correctly represent jobs scheduled from 1970 through 2037.

Job scheduling and execution with at and atrun
Apple reference # : 2263271

ISSUE:
Under certain circumstances, atrun did not correctly handle jobs scheduled with at after 1999.

RESOLUTION:
The at and atrun commands have been modified to correctly and consistently handle the scheduling and execution of jobs regardless of date.

Date display in /usr/ucb/mail
Apple reference # : 2259253

ISSUE:
In OPENSTEP 4.2, the Date: header of email messages written by /usr/lib/sendmail used a two-digit year in the creation time. This issue affected email created and read with the /bin/mail and /usr/ucb/mail programs.

RESOLUTION:
sendmail has been modified to write four-digit years in the date header.

ntpd Error Messaging
Apple reference # : 2260775

ISSUE:
Under OPENSTEP 4.2, the error message returned when an excessive offset was encountered did not report the year correctly for years after 1999.

RESOLUTION:
This error message now reports the year correctly.

PostScript: Display PostScript Options

Is there any third-party hardware that uses Display PostScript to draw the image on a Macintosh screen?

If there is no hardware, do you know of a software PostScript interpreter to preview PostScript files on a Macintosh screen?
This article has been archived and is no longer updated by Apple.
Display PostScript (licensed by Adobe) lets a PostScript procedure render graphics on a bit-map screen (in the same manner that a LaserWriter with its built-in PostScript lets a PostScript procedure render graphics on a sheet of paper).

Apple displays its graphics via QuickDraw instead of PostScript. Apple has no plans to display graphics based on PostScript language routines for many reasons. Providing this capability would likely require a rewrite of the Macintosh operating system.

If you are running A/UX, a PostScript user interface called NeWS may be used. A NeWS application is a collection of PostScript procedures that are sent to a NeWS server (perhaps remotely via a network connection). The server interprets the PostScript procedures and renders graphics in a window on the display's bit-map screen.

Macintosh print drivers let you view PostScript commands for editing purposes. If running System 6, press and hold the Command and "F" keys after selecting OK from the print dialog box. You'll see the message "Creating PostScript File." The file is named PostScript0, PostScript1, and so on - a standard text file that can be opened by most word processing and text editing programs. System 7 print drivers give you the option to change the print-job destination from the printer to disk. Merely check the appropriate destination in the print dialog.

It is possible to display an EPS (Encapsulated PostScript) file with many Macintosh applications, including Adobe Illustrator.

To display full PostScript files under the Macintosh OS, use an application like LaserTalk from Emerald City Software or PostShow from Lincoln & Co.

Search on company names for more information about third party products.

WebObjects 4: Adding Third-Party Classes to a WebObjects Project

This article discusses adding Java classes to a WebObjects application when the source code is not available.
This article has been archived and is no longer updated by Apple.
Q: I have some Java classes that I want to use in my WebObjects application, but I do not have the source code. How do I get WebObjects to recognize my Java classes?

A: Follow these steps:

1. Look in Project Builder for a Subprojects suitcase. If it is not there, use the Project-->New Subproject... menu item to create a new supbroject of type WebObjectsSubproject, named CommonJava. If there is a Subprojects suitcase and CommonJava is not listed in its browser, double-click the suitcase, choose the CommonJava.subproj directory, and add it to your project.

2. Highlight Subprojects --> CommonJava.subproj --> Resources, and drag your .jar, .zip, or .class file(s) into the Resources suitcase.

3. In your CommonJava.subproj Makefile.preamble, make sure you have the line:

```
JAVA_IS_SERVER_SIDE = YES
```

4. Edit Makefile.preamble at the top level of your project, and set OTHER_CLASSPATH.

- If you have a .jar file:
  `OTHER_CLASSPATH = $(shell pwd)/CommonJava.subproj/MyClasses.jar`
- If you have a .zip file:
  `OTHER_CLASSPATH = $(shell pwd)/CommonJava.subproj/MyClasses.zip`
- If you have a .class file:
  `OTHER_CLASSPATH = $(shell pwd)/CommonJava.subproj`

5. Back at the top level of your project, edit Supporting Files --> CustomInfo.plist, which should look something like this:

```
{
// ** Add your class paths here in the form of an array as follows:
NSJavaUserPath = (C:/MyStuff/MyApp.woa/Resources/MyClasses.jar);
}
```

This must be an absolute path; relative paths will not work.

6. For Solaris users only, set your LD_LIBRARY_PATH as follows:

```
setenv LD_LIBRARY_PATH $NEXT_ROOT/Library/JDK/lib; $NEXT_ROOT/Library/JDK/lib/sparc/native_threads
```

7. You're done; save the project and re-compile your application.

You need to set OTHER_CLASSPATH in Makefile.preamble to satisfy the Java compiler. However, you also need NSJavaUserPath to satisfy the Java runtime, because the third-party classes aren't statically linked into your app. You can set your CLASSPATH environment variable instead of setting NSJavaUserPath, but NSJavaUserPath is usually more convenient for deployment purposes.

EOF 2.2 User Patch 2 Overview

This document contains release notes for EOF 2.2 User Patch 2, an update to Apple's Enterprise Objects Framework on Windows NT and Solaris. This patch incorporates all EOF bug fixes released in EOF 2.2 Patch 1, the WebObjects 3.5.1 Database Adaptor Patches and the WebObjects Java Patch 2. This patch should **only** be applied to systems with EOF 2.2 installed. This patch only addresses user-level issues. EOF 2.2 developers should also see **article 70057** for more information on EOF 2.2 Developer Patch 2.

The WebObjects Current Patch List, **article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. The OPENSTEP Current Patch List, **article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read these documents if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.

Installing EOF 2.2 User Patch 2 on Windows NT 4.0

1. **Download** the Windows NT version of the patch from Apple's FTP site at ftp.info.apple.com. Also **download** the installer script, "patcher.nt.sh".

2. Log in as a user with Administrator privileges.

3. Open a Bourne shell. The Bourne shell should be available from your Start menu, under the WebObjects program group, or under your Apple root directory at
`NextLibrary\Executables\sh.exe`.

4. Change to the directory containing the patch and the patch installer, "patcher.nt.sh".

5. Type the following at the shell prompt (make sure that there are no EOF applications running first):
```
./patcher.nt.sh -install EOF22_NT_User_Patch2.TAR.gz
```

For more information on using the patcher.nt.sh program, type the following at the command prompt:
```
./patcher.nt.sh -help
```

6. Restart your Windows NT computer.

Installing EOF 2.2 User Patch 2 on Solaris

1. **Download** the Solaris version or of this patch from Apple's FTP servers at ftp.info.apple.com. Also **download** the installer script, "patcher.sh".

2. Log in as root. If you're not sure how to log in as root, see your system administrator.

3. Change to the directory containing the patch and the patch installer, "patcher.sh".

4. Type the following at the shell prompt (make sure that there are no EOF applications running first):
```
./patcher.sh -install EOF22_Solaris_User_Patch2.TAR.Z
```

For more information on using the "patcher.sh" program, type the following at the command prompt:
```
./patcher.sh -help
```

5. Restart your Solaris computer.

Issues Fixed

Corrected in EOF 2.2 User Patch 2

EOF applications crash accessing SQL Server 7

Apple reference # 2315234

ISSUE: EOModeler and other EOF-based applications crashed when trying to connect to Microsoft SQL Server 7.0.

RESOLUTION: The EOF ODBC adaptor has been updated, enabling EOF applications to connect to SQL Server 7 without error.

Java project recompilation

Apple reference # 2315243

ISSUE: In order to take advantage of a bug fix in an upcoming WebObjects patch, some EOF Java projects needed to be recompiled.

RESOLUTION: The relevant projects have been recompiled in this patch.

ODBC adaptor generates spurious login error message

Apple reference # 2315563

ISSUE: While defining a new model or switching a model's adaptor to ODBC, the first attempt to connect to the database failed and a misleading "invalid login" error message was displayed. However, if the user continued with the login, entering the correct user name and password, the login succeeded. Subsequent attempts to log in with the same model did not produce this false error message.

RESOLUTION: The connection information associated with the initial login panel is now properly constructed.

ODBC adaptor prepends owner to table name

Apple reference # 2319114

ISSUE: When reverse engineering a Microsoft SQL Server database with ODBC, the table names all had the form OWNER.NAME instead of just NAME.

RESOLUTION: The table names no longer have the owner prefixed to the name.

Editing context should not decrement snapshot retain count when forgetting a fault

Apple reference # 2326799

ISSUE: When an editing context was released, the snapshot retain count was decremented for all of its registered objects, both "real" objects and faults. Since the snapshot retain count is only incremented when "real" objects are registered, this caused the snapshot retain count to be too low for faulted objects. An exception might be raised later because the snapshot had been released prematurely.

RESOLUTION: EOEditingContext now decrements the snapshot retain count only for complete objects, not for faults.

Snapshot refcount not incremented correctly with Entity Caching turned on.

Apple reference #2327400

ISSUE: With entity caching enabled, the snapshot retain count was not correctly incremented when an entity was cached. Since the retain count was too low, a crash could result when attempting to access a cached entity whose snapshot had been released too soon.

RESOLUTION: The EOAccess framework now increments the snapshot retain count for each object in an entity when the entity is cached and decrements the snapshot retain count for each object when the cache is invalidated.

Corrected in EOF 2.2 Patch 1

OracleEOAdaptor generates incorrect SQL for left and right outer joins

Apple reference # 2165674, 2288089

ISSUE: The SQL generated by the Oracle adaptor for a left outer join was actually the syntax for a right outer join, and vice versa.

RESOLUTION: The Oracle adaptor now generates the correct SQL for left and right outer joins.

EODatabase never releases snapshots

Apple reference # 2169671, 2231693

ISSUE: Snapshots associated with enterprise objects were never released.

RESOLUTION: EOF now tracks references to an object and releases the object's snapshot when there are no more references to it

Newly inserted objects not deleted correctly

Apple reference # 2176466, 2253191

ISSUE: An object created and inserted into an editing context or relationship, then deleted before being saved to the database, was not completely removed from the editing context. This caused an exception to be raised the next time the editing context was saved.

RESOLUTION: Deletion of a newly-inserted object now completely removes the object from the editing context.

Optimistic locking fails on rows with trailing spaces

Apple reference # 2177721, 2231704

ISSUE: OracleEOAdaptor stripped trailing spaces from VARCHAR2 data fetched from or committed to an Oracle database. If VARCHAR2 data containing trailing spaces had been inserted by another tool, optimistic locking failed for any affected row and the row could not be updated.

RESOLUTION: OracleEOAdaptor no longer strips trailing spaces from VARCHAR2 data.

Incorrect NSNumber formatting for zero values

Apple reference # 2181645, 2264031

ISSUE: Zero values for number fields displayed by EOF did not always have appropriate formats for their types. For example, some integer zero values were represented as "0.00".

RESOLUTION: EOEntity has been modified to format zero values appropriately for all number types.

Logic error in EOAccess layer sometimes raises exception while generating primary keys

Apple reference # 2182084, 2278561

ISSUE: Under certain circumstances, the EOAccess code that generates primary keys sent a message to inappropriate objects causing a "NoSuchMethodError" exception to be thrown in Java or one of several exceptions to be raised in Objective C.

RESOLUTION: EOAccess now checks the class of the receiver before sending the message that was causing the issue.

EOModeler can't create a model with EODeleteRuleNoAction

Apple reference # 2202107, 2248443

ISSUE: In EOModeler's AdvancedRelationship inspector, if the Delete Rule was set to "No Action", the following warning was posted the next time the model was opened:

```
Invalid delete rule string:'EODeleteRunNoAction' on entity with name: '<entity_name>'
```

This issue could also affect applications which create their own models.

RESOLUTION: This issue was caused by a simple typographical error which has been corrected. It is now possible to create models with EODeleteRuleNoAction.

EOQualifier qualifierWithFormat methods conflict

Apple reference # 2203613, 2275802

ISSUE: If a qualifier was created using `+[EOQualifier qualifierWithQualifierFormat: arguments:]` and, subsequently, another qualifier was created using `+[EOQualifier qualifierWithQualifierFormat:]`, a parse error occurred, even if the second qualifier was valid.

RESOLUTION: The interference between these two methods has been removed and they now operate correctly.

selectObject: method return values don't match documentation

Apple reference # 2205357, 2275804

ISSUE: The `[EODisplayGroup selectObject:]` method would only returned 'NO' if it could not end editing or if the delegate refused the change. According to the class documentation, it should also return 'NO' if the EODisplayGroup's displayedObjects array does not contain a match with the method's object argument.

RESOLUTION: As stated in the documentation, this method now also returns 'NO' when it cannot find a match for the argument object.

Sybase can't fetch float and text data together

Apple reference # 2208497, 2259088, 2274601

ISSUE: The Sybase adaptor could not fetch data of types text and float together.

RESOLUTION: The adaptor has been fixed so that there is no longer a conflict between these data types.

EOControl layer raises exception while building qualifier

Apple reference # 2213188, 2271206

ISSUE: The qualifier parsing code in the EOControl layer incorrectly sends copyWithZone: to custom enterprise objects under certain conditions, causing a "selector not implemented" exception to be raised in Objective C or a "CloneNotSupportedException" to be thrown in Java.

RESOLUTION: copyWithZone: is no longer called on custom enterprise objects when building a qualifier.

Nil value in EOAttribute causes crash while saving EOModel

Apple reference # 2220588, 2274226

ISSUE: In certain circumstances, a crash occurred during the save of an eomodel because a nil serverTimeZone attribute was being inserted into the eomodel.

RESOLUTION: The EOAccess layer has been changed to test for and handle a nil value for this attribute.

Exception while writing an eomodel to disk corrupts the model

Apple reference # 2220893, 2274225

ISSUE: If an exception was raised while an eomodel was being written to disk, the original model was lost and only the partially-written or corrupted model was left on the disk.

RESOLUTION: A backup copy of the eomodel is now made before the write begins. If an error occurs during the write the partially-written file is saved as `<model_name>.eomodeld#` and the original eomodel is restored from the backup.

Prefetching can mysteriously fail

Apple reference # 2223730, 2264033

ISSUE: Prefetching would sometimes failed for no apparent reason, due to inappropriate filtering of relationships inside the EOAccess layer.

RESOLUTION: The incorrect filtering on prefetches has been removed from EOEntity.

Unnecessary firing of to-many faults

Apple reference # 2227660, 2248080

ISSUE: If the PropagatePrimaryKey flag on an EOEntity was set to YES, saving changes to the EOEditingContext caused array faults for all of that entity's to-many relationships to be fired. This was not necessary and could cause performance issues.

RESOLUTION: The EOAccess layer has been changed so that it no longer fires unnecessary faults.

EOFault retain/release behavior conflicts with Java bridge

Apple reference # 2239504, 2297785

ISSUE: EOFault's special handling of retain and release sometimes caused conflicts with the Java bridge.

RESOLUTION: The retain and release behaviours of EOFault have been modified to interoperate correctly with Java via the bridge.

Incorrect Sybase smallint mapping

Apple reference # 2241377, 2247522

ISSUE: On HP-UX and Solaris, data with the Sybase type smallint was mapped to NSNumber/Integer and assigned the original value times 2 ^16 when retrieved from a Sybase database.

RESOLUTION: The Sybase adaptor now correctly maps smallint data to type NSNumber/Short and does not modify the value.

No EOActionCellAssociation for most controls

Apple reference # 2243956, 2269874

ISSUE: EOActionCellAssociation did not work with controls other than NSTextField in EOF 2.2 and WebObjects 3.5.1.

RESOLUTION: This class has been changed to work with NSButtons and other controls, as well as NSTextFields.

Can't use Sybase 11 stored procedures

Apple reference # 2244533, 2274650

ISSUE: The Sybase adaptor was unable to interpret stored procedures created in Sybase 11.

RESOLUTION: The adaptor has been fixed to work properly with stored procedures from both Sybase 10 and Sybase 11.

Case-insensitive matching sometimes fails

Apple reference # 2248977, 2275805

ISSUE: Case-insensitive matching in EOQualifier did not correctly match uppercase letters in the search pattern with lowercase letters in the receiving string.

RESOLUTION: EOQualifier has been fixed. [EOQualifier isCaseInsensitiveLike:] now works correctly.

EOEntity methods raise exceptions

Apple reference # 2251180, 2256685

ISSUE: Under some circumstances some methods of EOEntity, including setAttributes, setClassProperties, setRelationship, and removeRelationship, did not clear a private variable, potentially resulting in an application exception.

RESOLUTION: These methods now handle their private instance variables correctly.

Oracle adaptor state not reset when closing the database channel fails

Apple reference # 2252175

ISSUE: If the Oracle adaptor encountered an error while closing the database channel, the adaptor state was not reset correctly. As a result, the database connection could not be re-established on that channel once the database came back up.

RESOLUTION: The Oracle adaptor now sets its internal state correctly before raising the error, allowing the connection to be re-established once the database is restored.

Multiple propagation primary keys create race condition

Apple reference # 2260541, 2267964

ISSUE: Saving changes to two databases when both had a propagation primary key would not work in previous versions of EOF. A race condition occurred and only one database was able to generate primary keys.

RESOLUTION: EODatabaseContext has been changed to correct this behavior. Both databases can now generate their primary keys correctly.

Special characters crash Sybase adaptor

Apple reference # 2260785, 2261262

ISSUE: The SybaseEOAdaptor crashed when saving Text or BLOB data containing characters which could not be successfully encoded using the specified database encoding.

RESOLUTION: The adaptor has been fixed to detect the encoding failure and raise an exception, so that a database encoding which is able to handle the issue characters may be specified in the connection dictionary.

Can't use smallints as arguments to Sybase stored procedures

Apple reference # 2262888, 2274608

ISSUE: The Sybase adaptor did not allow the use of smallints as arguments to stored procedures.

RESOLUTION: The Sybase adaptor now allows stored procedures with smallint arguments.

Java garbage collecting fails with EOEditingContext

Apple reference # 2264063, 2264251, 2270489

ISSUE: EOEditingContext did not retain its registered objects. This could cause issues with Java garbage collection.

RESOLUTION: EOEditingContext now allows users to specify whether editing contexts retain their objects or not with the new class methods setInstancesRetainRegisteredObjects:flag:, getInstancesRetainRegisteredObjects, and reset. For API details, please see EOEditingContext.h. By default, in applications which contain Java, the editing context does retain all registered objects.

Deallocating an EODatabase containing snapshots causes crash

Apple reference # 2265751, 2272549

ISSUE: EODatabase released its snapshots too early during deallocation, causing a fatal exception to be raised if any snapshots were present.

RESOLUTION: The order in which instance variables are released by EODatabase has been corrected.

Memory leak in EODisplayGroup

Apple reference # 2217263, 2256402

ISSUE: A private variable was not being released in EODisplayGroup, causing a memory leak.

RESOLUTION: This variable is now released correctly.

Informix adaptor crashes on failed referential integrity check

Apple reference # 2272207, 2274351

ISSUE: If the InformixEOAdaptor was unable to find matching source and destination entities of a referential integrity constraint, it passed a nil pointer to the database, causing a crash.

RESOLUTION: The InformixEOAdaptor now detects this condition and handles it appropriately.

Incorrect time zone conversions in the SybaseEOAdaptor

Apple reference # 2276899, 2276907

ISSUE: When converting a time value to the server time zone, the SybaseEOAdaptor only substituted the server's time zone without actually adjusting the time value for the zone difference.

RESOLUTION: SybaseEOAdaptor now performs the conversion of the time value to the corresponding value in the server's time zone.

Can't subclass entities with fetch specifications

Apple reference # 2278492, 2279849

ISSUE: Due to an error in EOKeyValue encoding, EOModeler was unable to create a subclass when a fetch specification was associated with the entity being subclassed.

RESOLUTION: The encoding is now correct and entities with associated fetch specifications can be subclassed from within EOModeler.

Deleting objects with "toManyToOne" relationships sometimes fails.

Apple reference # 2278795, 2287021

ISSUE: In some circumstances, EOF did not correctly handle deletion of an object with a toManyToOne relationship, leaving rows in intermediate tables which should have been deleted.

RESOLUTION: The EOAccess layer now does a more thorough analysis of an object's relationships when it is deleted, and data in intermediate tables is correctly removed.

BusinessLogic framework fails to retain some global IDs

Apple reference # 2290233, 2290236

ISSUE: Several classes in the BusinessLogic framework example failed to retain global IDs for some enterprise objects, resulting in messages being sent to unexpectedly freed objects.

RESOLUTION: The classes now retain global IDs appropriately.

Editing the owning relationship in a nested editing context more than once corrupts the database snapshots.

Apple reference # 2280979, 2287025

ISSUE: Due to an error in the processing of array faults by the database context, editing the owning relationship in a nested editing context more than once corrupted the database snapshot for the owning object, resulting in database corruption.

RESOLUTION: The error in EODatabaseContext has been corrected.

EODisplayGroup instances leak

Apple reference #2286314

ISSUE: Each EODisplayGroup instance leaked two EOObserverProxy objects.

RESOLUTION: This leak in EODisplayGroup has been fixed.

Incorrect time zone conversion in EOAccess layer.

Apple reference #2287379

ISSUE: When converting a time value to the server time zone, the EOAccess layer substituted the server's time zone without actually adjusting the time value for the zone difference.

RESOLUTION: EOAttribute now performs the conversion of the time value to the corresponding value in the server's time zone.

Corrected in EOF 2.2 Sybase Adaptor Patch

All parameters required for Sybase stored procedures

Apple reference # 2203081

ISSUE: If you did not supply all values when executing a Sybase stored procedure, the execution would fail with an exception like:

```
Feb 19 11:23:53 WOF_3_5_Sybase_Patch[1027] Caught exception:EOGeneralAdaptorException

Sybase: Server:unknown Procedure:NEXT_MOVIE_PRIMARY_KEY Line:0 Procedure NEXT_MOVIE_PRIMARY_KEY expects
parameter @A_MOVIE_ID, which was not supplied.
```

This happens even though `A_MOVIE_ID` is not required for the stored procedure.

RESOLUTION: The Sybase adaptor no longer requires optional arguments to stored procedures.

Corrected in EOF 2.2 ODBC Adaptor Patch

ODBC Adaptor cannot execute stored procedures with output parameters

Apple reference # 2208503

ISSUE: The EOF 2.2 (WebObjects 3.5) version of ODBCEOAdaptor.framework introduced a bug which causes an error when using a stored procedure with an output parameter.

RESOLUTION: The ODBC adaptor now handles output parameters correctly.

ODBC adaptor leaks connections with Microsoft Access

Apple reference # 2209574

ISSUE: The EOF 2.2 (WOF 3.5) and earlier versions of ODBCEOAdaptor.framework did not release ODBC connections when using Microsoft Access (or any JET based data source) in order to work around a bug in the Microsoft odbcjt32.dll library; this bug caused a crash when SQLFreeConnect was called. The SQLFreeConnect bug was discovered in version 3.40.2829 of the DLL. Newer versions of the DLL (beyond 3.50) no longer exhibit the crashing issue.

RESOLUTION: The patched version of this framework now checks the version of the DLL more carefully and allows SQLFreeConnect to be called unless the DLL version is 3.4X. The adaptor no longer leaks the ODBC Connection when running with fixed versions of odbcjt32.dll.

EOF 2.2 Developer Patch 2 Overview

This document contains release notes and download information for EOF 2.2 Developer Patch 2, an update to Apple's Enterprise Objects Framework database access package for users of Windows NT and Solaris. This patch only addresses development issues; you should also download and install EOF 2.2 User Patch 2, which will update the user components of EOF 2.2. See **TIL article 70056** for more information.

The WebObjects Current Patch List, **TIL article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read these documents if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.

Installing EOF 2.2 Developer Patch 2 on Windows NT 4.0

1. Download the Windows NT version of the patch from Apple's FTP site at ftp.info.apple.com. Also **download** the installer script, "patcher.nt.sh".

2. Log in as a user with Administrator privileges.

3. Open a Bourne shell. The Bourne shell should be available from your Start menu, under the WebObjects program group, or under your Apple root directory at NextLibrary\\Executables\\sh.exe.

4. Change to the directory containing the patch and the patch installer, "patcher.nt.sh".

5. Type the following at the shell prompt (make sure that there are no EOF applications running first):

```
./patcher.nt.sh -install EOF22_NT_Dev_Patch2.TAR.gz
```

For more information on using the patcher.nt.sh program, type the following at the command prompt:

```
./patcher.nt.sh -help
```

6. Reboot your Windows NT system

Installing EOF 2.2 Developer Patch 2 on Solaris

1. Download the Solaris version of this patch from Apple's FTP servers at ftp.info.apple.com. Also **download** the installer script, "patcher.sh".

2. Log in as root. If you're not sure how to log in as root, see your system administrator.

3. Change to the directory containing the patch and the patch installer, "patcher.sh".

4. Type the following at the shell prompt (make sure that there are no EOF applications running first):

```
./patcher.sh -install EOF22_Solaris_Patch2.TAR.Z
```

For more information on using the "patcher.sh" program, type the following at the command prompt:

```
./patcher.sh -help
```

5. Reboot your Solaris system

Problems Fixed

Corrected in EOF 2.2 Developer Patch 2

EnterpriseObjects examples Rentals data contains an invalid date value
Apple reference # 2323510

PROBLEM:
The data with which the Rentals database is populated in the EnterpriseObjects examples contained an invalid credit card expiration year, 2597. With SQL Server 7.0, Microsoft's ODBC Driver failed when trying to convert this date value to the smalldatetime type, causing the examples' install_database script to fail and the Rentals data to be incompletely installed.

RESOLUTION:
The problem date has been changed to a value within SQL Server 7.0's valid year range (1900-2079).

Corrected in EOF 2.2 Patch 1

Development tools may attempt to load an eomodel file twice for an application nested within an aggregate project
Apple reference # 2267783, 2176591

PROBLEM:
When an application was nested in an aggregate project, the development tools attempted, due to an error in the path searching code, to load an EOModel file twice .

RESOLUTION:
The logic used to locate model files now works correctly in the case of aggregate projects. Model files are loaded only once.

EOWizard not localizable
Apple reference # 2231705, 2177282

PROBLEM:
Certain resources needed for localization in EOWizard were not located in the correct place.

RESOLUTION:
Template files required for localizing the wizard have been moved from the framework's Resources directory to the ../Resources/English.lproj directory, making it possible to localize these resources.

OPENSTEP and NeXTSTEP SPARC Hardware Compatibility Guide

This document describes in general terms the types of Sun Sparc hardware supported by NeXTSTEP Release 3.3 and OPENSTEP for Mach release 4.x.

NOTE: Apple Enterprise Software has suspended on-going development of new drivers and hardware support for the NeXTSTEP and OPENSTEP product lines. If you have specific requirements for drivers for hardware not currently supported, contact your AES sales representative for a quote for custom development work.

GENERAL SYSTEM REQUIREMENTS

CPU

- Sun microSPARC II, SuperSPARC II, and SuperSPARC single processor workstations (see http://www.sun.com/) models
- SPARCstation 4: 85
- SPARCstation 5: 85 & 110
- SPARCstation 10: 50, 60, & 90
- SPARCstation 20: 50, 51, 61, & 71

AVAILABLE HARD DISK SPACE

- User Environment:150 MB minimum, 250 MB recommended for stand-alone systems.
- User + Developer: Environments: 330 MB minimum, 400 MB recommended.

RAM REQUIREMENTS

RAM requirements vary depending upon the user's selection of graphics adapter. NEXTSTEP Release 3.3 supports a maximum of 256MB of memory.

- 24-bit color: 16 MB RAM Mininum, 32 MB RAM Recommended
- 8-bit grayscale/color: 16 MB RAM Minimum, 24 MB RAM Recommended

GRAPHICS ADAPTERS

8-bit color and grayscale at 1152x900 or 24-bit color at 1152x900 with appropriate video system. Release 3.3 supports multiple monitors with graphics cards for expanded desktop space.

MASS STORAGE

Floppy disk drive, SCSI hard disk drives, CD-ROM drives, 1/4 inch tape drives, Exabyte tape drives, and DAT tape drives are supported.

KEYBOARD & POINTING DEVICES

Sun keyboard and Sun optical or mechanical mouse.

PRINTERS

PostScript printers connected via a serial or parallel port. Color PostScript Level II printers are recommended for proper color support.

NETWORKING

Thick, thin, and twisted pair ethernet on board interfaces are supported. Ethernet transceivers may be necessary for installation at particular sites.

SOUND

16-bit audio at 22 and 44 khz is supported.

INSTALLATION

A Sun SCSI CDROM, or a supported network adapter and properly configured network installation host are required for installation of NEXTSTEP.

Supported Configurations

SPARCstation 4

- Graphics: 8 bit grayscale & color @ 1152x900
- Sound: On-board 16 bit sound @ 48kHz with Mic. plug-in
- Networking: On-board ethernet (TP and AUI)
- Bus: 1 SBus

SPARCstation 5

- Graphics: 8 bit grayscale & color @ 1152x900 with GX, Turbo GX, & Turbo GX+; 24 bit color @ 1152x900 with S24 on AFX bus
- Sound: On-board 16 bit sound @ 48kHz with Mic. plug-in
- Networking: On-board ethernet (TP)
- Bus: 3 SBus & 1 AFX Connector for Video card

SPARCstation 10

- Graphics: 8 bit grayscale & color @ 1152x900 with Turbo GX and Turbo GX+; 24 bit color @ 1152x900 with SX
- Sound: On-board 16 bit sound @ 48kHz with Mic. plug-in and sound box
- Networking: On-board ethernet (TP)
- Bus: 4 SBus

SPARCstation 20

- Graphics: 8 bit grayscale & color @ 1152x900 with Turbo GX and Turbo GX+; 24 bit color @ 1152x900 with SX
- Sound: On-board 16 bit sound @ 48kHz with Mic. plug-in
- Networking: On-board ethernet (TP)
- Bus: 4 Sbus

WebObjects 4: Password Protecting the WOStatsPage

The WOStats page gives a WebObjects application administrator useful information about their application and its real-world usage. This document explains how to use password protection to keep external requests from accessing your site's statistics page.
This article has been archived and is no longer updated by Apple.

Overview

By default, the password protection functions of WOStats are disabled. To enable them, you will need to change some of the files in the WOStatsPage project. The exact steps will depend on your operating system. After the function is enabled, it is easy to set a password in your application.

Enabling Password Protection on MacOS X Server

To enable password protection on MacOS X Server, first open the file

```
System/Library/Frameworks/WOExtensions.framwork/Resources/WOStatsPage.wo
```

in the WOBuilder application. If you do not have the development tools installed on this system, you will have to edit the files by hand; follow the instructions for Solaris and HP-UX systems, below.

- After the file is open, switch to the "Text Mode" view. This will display the HTML file in the upper window, and the application .wod file in the lower window.
- In the upper (HTML) window, line 10 is an HTML comment opening code, "<!--". Remove this line and the matching end comment line after the password object.
- In the lower window, find the ALLOWED: WOConditional statement. The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

- In the same window, find the "REFUSED: WOConditional" statement. The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

Password protection is now enabled. Follow the instructions below to set a password for your application.

Enabling Password Protection on Solaris or HP-UX

To enable password protection on a Solaris or HP-UX system, first open this directory under your Apple root directory (usually /Apple or /opt/Apple):

```
Library/Frameworks/WOExtensions.framwork/Resources/WOStatsPage.wo
```

This directory will contains two files, WOStatsPage.html and WOStatsPage.wod. Using a text editor, make the following three changes:

- Line 10 of the WOStatsPage.html file is an HTML comment opening code, "<!--". Remove this line and the matching end comment line after the password object.
- In the WOStatsPage.wod file, find the "ALLOWED: WOConditional" The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

- Also in the WOStatsPage.wod file, find the "REFUSED: WOConditional" statement. The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

Password protection is now enabled. Follow the instructions below to set a password for your application.

Enabling Password Protection on Windows NT 4.0

To enable password protection on Windows NT, first open this directory under your Apple root directory (usually C:\\Apple):

```
Library/Frameworks/WOExtensions.framwork/Resources/WOStatsPage.wo/
```

This directory will contains two files, WOStatsPage.html and WOStatsPage.wod. Using a text editor or WOBuilder, make the following three changes:

- Line 10 of the WOStatsPage.html file is an HTML comment opening code, "<!--". Remove this line and the matching end comment line after the password object.
- In the WOStatsPage.wod file, find the "ALLOWED: WOConditional" statement. Uncomment the next line and comment out the line that reads:

```
condition=YES;
```

The statement should now read:

```
ALLOWED: WOConditional {
condition=session.allowedToViewStatistics;
//condition=YES;
}
```

- Also in the WOStatsPage.wod file, find the "REFUSED: WOConditional" statement. Uncomment the next line and comment out the line that reads:

```
condition=YES;
```

The statement should now read:

```
REFUSED: WOConditional {
condition=session.allowedToViewStatistics;
//condition=YES;
nagate="1";
}
```

Password protection is now enabled. Follow the instructions below to set a password for your application.

Using Password Protection

Once password protection is enabled, set the password in your Application.wos file's **init** method. The syntax is:

```
[[self statisticsStore] setPassword: @"MyPassword"];
```

WebObjects 4.0.1: DirectToWeb Assistant Error Workaround

The workaround described in this article has been included in WebObjects 4.0.1 Patch 2 and subsequent patches. Please see the WebObjects Current Patch List, article **70037**, for information on the most current patches for WebObjects and Enterprise Objects Framework. This obsolete article is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.
Note: Any reference to Mac OS X Server in this article pertains to version 1.2, which was released prior to May 2001.

Q: I am using DirectToWeb on Mac OS X Server with WebObjects 4.0.1. When I try to use the Assistant to generate a page, the following exception message will appear:

```
[DTWTemplate writeAndAddToProjectComponentNamed:]: selector not recognized
```

A: This is a known bug with DirectToWeb, Apple reference number 2315706. To avoid this bug, you will need to download and install an updated version of one of the Mac OS X Server library files. To install the updated library:

1. **Download** the Mac OS X Server version of the patch from Apple's FTP site at ftp.info.apple.com. The file is located at:

```
/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/webobjects/

patches/4.0.1/libDTWGeneration.A.dylib.tar
```

2. Uncompress the file. The filename should be **libDTWGeneration.A.dylib**

3. Use **su** to log in as the root user

4. Change to the **/usr/lib/java** directory

5. Back up the current **libDTWGeneration.A.dylib** file

6. Replace the current **libDTWGeneration.A.dylib** file with the file you just downloaded

You can now use the Assistant to generate new web pages.

HyperCard: Dial Sounds Different with System 6.0.5

I have a new Macintosh LC, and a HyperCard note stack I've used for the past six months, which includes phone dialing routines. The dialer, which I've used by holding my handset to the speaker of a Macintosh IIx, no longer works. Tones are generated, but regardless of the distance between the Macintosh speaker and phone mouthpiece, they don't trigger the phone system. I've done some audio comparison tests, and it sounds as if the LC's tone generator is inaccurate, perhaps as much as a quarter-tone high.

This article has been archived and is no longer updated by Apple.
As a result of changes in the Macintosh OS, support for DTMF tones is no longer available. HyperCard 2.0 uses digitized sounds with the Dial command. HyperCard 1.2.x will have difficulty producing the exact tones required to trigger the telephone system. Upgrading to HyperCard 2.0 should solve the problem.

You may want to consider the following:

* Try dialing with pauses between the tones. Commas in the string cause a one-second delay.

* A direct connection to the Macintosh results in higher fidelity and may trigger the phone system. The Macintosh sound circuitry is capable of producing much higher-quality sound than the speaker can pass. HyperDialer connects directly to the sound port and eliminates both our speaker and the telephone microphone.

WebObjects 4: Solaris "Can‘t find Xa.o" error message

Q: When I try to compile my WebObjects 4 application on a Solaris 2.6 system, I get the error message:

```
Link error, can't find Xa.o
```

My app compiles and links without this problem on other platforms. What's wrong?

This article has been archived and is no longer updated by Apple.
A: Some Solaris 2.6 distributions did not include the operating system package

```
System SUNWarc Archive Libraries
```

which is required by the WebObjects linker. The archive libraries are included in your Sun distribution and can be added to your system with the "pkgadd" command.

WebObjects 4: Cross-Model Relationships And the Java Client

In WebObjects 4, there is a known bug with the EOF Wizard, Apple reference # 2178911. This document describes how to work around this bug and generate the missing Java client subproject.
This article has been archived and is no longer updated by Apple.
Note: Any reference in this article to Mac OS X Server pertains to version 1.2, which was released prior to May 2001.

The Problem

There is a known problem in WebObjects 4 concerning the Wizard panel. When creating a WebObjects application with the Wizard, if you:

- Select "Java Client" as your application type
- Choose an EOModel file that contains cross-model relationships to another EOModel file

instead of giving the user the option of selecting a template, such as EOF Application Skeleton, Single Table, or Master-Detail, the Wizard will silently go straight to Project Builder. None of the ClientJava.subproj files will be generated.

The Workaround

To work around this bug and create a Java Client project that contains models with cross-model relationships, or models that reside in frameworks:

- Start Project Builder and create a new WebObjects Application with the New... menu command.
- Choose "None" for Available Assistance and "Java" as the Primary Language in the WebObjects Application Wizard.
- Remove the ClientSideJava.subproj that is automatically created when you create your project. Use the Delete command from Windows NT Explorer (if working on NT) or the Delete command in the File Viewer (if working with Mac OS X Server). You will not be able to delete this subproject from within Project.
- Create a new subproject named ClientSideJava of type EOJavaClient subproject with ProjectBuilder "New SubProject..." command.
- Go to the Interfaces class folder inside the ClientSideJava.subproject, and use Project Builder's File -> New in Project command to generate a new Interface file.
  Please note that by convention, the interface file name in the ClientSideJava subproject is the same as the application name. For example, for an application named MyApp, your interface file should be named MyApp.nib.
- Put the eomodel file you want to use into the Project Builder Resources folder.
- The WebObjects Java Client Interface Wizard will come up. You can now specify the EOModeler file to be used.
  The wizard will create an English.lproj directory and the .nib file skeleton that you want.

Note: Please remember to add EOJavaClient.framework under the Frameworks directory of Project Builder; otherwise, your compilation will fail.

WebObjects 4: Control-Dragging in Windows NT Project Builder

Q: On other platforms, I can control-drag files to sort them in the Project Builder file browser. This doesn't seem to work on Windows NT versions of Project Builder. How can I enable this feature on Windows NT?
This article has been archived and is no longer updated by Apple.
A: To enable control-dragging on Windows NT, type the following at a Bourne shell:

```
defaults write NSGlobalDomain NSModifierFlagMapping "{LeftControl=Command;RightControl=Control;LeftAlt=Alt;RightAlt=Alt}"
```

This allows you to use the the right control key (or any key you set to "Control") to control-drag files in Project Builder on Windows NT. You can also set this mapping in the Project Builder domain if you only want it to apply to Project Builder. Using NSGlobalDomain will apply it to all of the current user's applications.

For more information on customizing WebObjects' text system, see the TextDefaultsAndBindings documentation in the Programming Topics section of WOInfoCenter.

WebObjects 4: Using the NSGregorianDateFormatter

This document discusses how to create and use an NSGregorianDateFormatter under WebObjects 4.
This article has been archived and is no longer updated by Apple.
Q: I'm trying to use a NSGregorianDateFormatter to format dates. I'm following the procedure suggested in the documentation, but I get an error message when I try to use the date formatter. What am I doing wrong?

A: Make sure you're applying the NSGregorianDateFormatter to the date, and not to the enclosing object. The correct way to use an NSGregorianDateFormatter is:

```
// construct a date, then turn it into a string with toString()
String aDateString;
aDateString = (new NSGregorianDate()).toString();
NSGregorianDate aDate;

// use whatever formatting that you want...
NSGregorianDateFormatter aDateFormat = new NSGregorianDateFormatter("%m/%d/%Y", false);

// format your date
aDate = (NSGregorianDate)aDateFormat.objectValueForString(aDateString);
```

WebObjects 4: Oracle Adaptor for Mac OS X Server

The Oracle adaptor described in this article has been included in WebObjects 4.0.1 Patch 2 and subsequent patches. Please see the WebObjects Current Patch List, article **70037**, for information on the most current patches for WebObjects and Enterprise Objects Framework. Apple recommends that WebObjects 4.0.1 users install the current patch rather than downloading the Oracle adaptor directly. This obsolete article is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.
Note: Any reference in this article to Mac OS X Server pertains to version 1.2, which was released prior to May 2001.

About This Patch

This is an update to WebObjects 4.0.1 for Mac OS X Server. The Oracle Adaptor allows WebObjects applications on Mac OS X Server to access Oracle database servers on the network. This package contains no changes for WebObjects on other platforms.

Installing the Oracle Adaptor for Mac OS X Server

1. Download the adaptor from Apple's FTP site at ftp.info.apple.com.

2. Uncompress the Mac OS X Server package file. Your web browser or FTP client may perform this step for you.

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Double-click on the OracleEOAdaptorUpdate.pkg file. Make sure that no other applications are running before you do this step.

5. Click the Install button in the Installer package window. An Install Package panel will open.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, **click OK** to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

7. Find the WOInfoIndexer executable in the Workspace Manager and double-click on it. This runs an indexing script so that Oracle Adaptor documentation will be available through WOInfoCenter.

WebObjects 3.5.1: Using Solaris Frameworks

Under Solaris, frameworks are a simple wrapper around standard shared libraries. Apple uses the Solaris dlopen(3x) call to load in frameworks. This document explains in more detail how to work with frameworks under Solaris. This article assumes that you are using WebObjects 3.5.1. This article has been archived and is no longer updated by Apple.

How Solaris Shared Libraries Work

Shared libraries are given a name during link time (see ld and the -h flag). This name can either be a path (a string with a '/') or a simple name (a string without a '/'). If the library is linked with a path then that path is the only place that the library will be searched for, no run time flags can be given to make Solaris look elsewhere. If the library is linked with a simple name then several directories are searched, starting with any directory named in the LD_LIBRARY_PATH env variable, any directory specified with the -R flag when linking the WOF app and then /usr/lib.

Default Framework Behavior in WOF 3.5.1

The default behavior in WOF 3.5.1 is to link frameworks with a hardcoded path name of:

```
/XXX.framework/Versions/YYY/XXX
```

where **XXX** is the framework name and **YYY** is the framework version. Since the framework was linked with a fully defined path name the only place that it can be installed is in the root directory.

How to Modify the Default Behavior

The shared library's name can be changed with the INSTALL_NAME_DIRECTIVE of Makefile.postamble. The format of this directive is as follows

```
INSTALL_NAME_DIRECTIVE = -install_name XXXX
```

where XXXX is the name that gets added to the -h flag. During development of your app you should set the INSTALL_NAME_DIRECTIVE to a blank string. This will cause the framework to get link in with a path that is hardcoded to whatever place the framework will be after it is linked in. This makes it easy to test out your executables without having to worry about where your frameworks should go after building.

If you know exactly where you want to install your frameworks and are not worried about moving them in the future just set the INSTALL_NAME_DIRECTIVE to a hardcoded path name. For example if you want to install version A of the DATA framework in the /opt /Frameworks directory set the directive as follows

```
INSTALL_NAME_DIRECTIVE = -install_name /opt/Frameworks/DATA.framework/Versions/A/DATA
```

If you want total freedom over where to install your frameworks you can set the INSTALL_NAME_DIRECTIVE to be a simple name. For example with the DATA framework set the directive as follows

```
INSTALL_NAME_DIRECTIVE = -install_name DATA
```

Before you run your WOF app you need to define the LD_LIBRARY_PATH env variable to the location of the framework

```
setenv LD_LIBRARY_PATH /opt/Frameworks/DATA.framework/Versions/A/
```

or you can add the following to the Makefile.preamble of your main WOF app

```
OTHER_LDFLAGS = -R /opt/Frameworks/DATA.framework/Versions/A
```

Another solution would be to provide the INSTALL_NAME_DIRECTIVE a relative path to your frameworks. For example if you are going to install the DATA framework in the same directory as the main WOF app you can set the INSTALL_NAME_DIRECTIVE as follows

```
INSTALL_NAME_DIRECTIVE = -install_name DATA.framework/Versions/A/DATA
```

MacDFT Group 1: Timer and Performance Over Token Ring

What happens when you change the Group 1 timer values on the Token Ring card? People here are complaining about the speed of MacDFT compared to the PS/2's that they had connected on the network. Would changing the values have any effect on the response time of MacDFT over Token Ring?

This article has been archived and is no longer updated by Apple.

We don't recommend changing the Response and Acknowledge timers, unless you really know what you are doing. You can experiment with the Inactivity Timer, if you often get timeouts from the hosts. While selecting the MacDFT Config CDEV, pressing Command-T brings up the Group 1 Timers window with three timers. Only experiment with the Inactivity Timer, which is the bottom value. We don't expect changing these values would increase the performance of MacDFT.

The performance differences between the machines is not due to the block or even packet size (if both systems are on Token Ring), but is most likely due to MacDFT's intrinsic program speed. However, if the PS/2 is a LU and is "directly" connected to the controller, and, if the Macintosh is a PU having to go through a gateway, there can be substantial performance differences. Or if the PS/2 is on Token Ring, and the Macintosh is on coax, the PS/2 will be faster. But again, if everything else is equal, the Macintosh will still be slower.

In file transfer for example, under TSO when you transfer a file you allocate space in blocks, tracks, or cylinders by specifying BLKS, TRKS, or CYLS. Under CMS this is done automatically, depending on the file type you select, and can't be changed by the client. And even under TSO when you allocate the space, this doesn't influence perceptibly the throughput performance.

Data is sent one buffer-full at a time, and the buffer size is set to be the screen size. So, if your terminal is configured to have a 80*24 screen, during file transfer approximately 1920 bytes will be transferred at a time.

WebObjects 4: NSLog and Slow NT Application Response Time

The workaround described in this article has been included in WebObjects 4.0.1 Patch 2 and subsequent patches. Please see the WebObjects Current Patch List, TIL article **70037**, for information on the most current patches for WebObjects and Enterprise Objects Framework. This obsolete article is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.
This article has been archived and is no longer updated by Apple.
Q: I've upgraded my Windows NT installation from WebObjects 4.0 to WebObjects 4.0.1, and some of my applications are much slower than they were on 4.0. How can I fix this problem?

A: There is a known problem with NSLog in WebObjects 4.0.1. In some cases, NSLog statements can take as much as thirty seconds to execute. To see if you are encountering this problem, try adding this code (or its Java equivalent) to your application's main function:

```
int index;
for (index=0; index<100;index++)
 NSLog(@"HELLO");
```

If this slows your application down significantly, you are most likely encountering this bug. Apple is actively working on a patch for this problem; more information will be posted here when the patch is available. Until the patch is ready, a workaround is to manually replace NSLog() with an equivalent function that does not experience these delays. For example, incorporate the following code into main:

```
extern void _NSSetLogCStringFunction(void(*)(const char *, unsigned, BOOL));

static void _GarbageFreeLogCString(const char *message, unsigned length,
BOOL withSyslogBanner) {
   fprintf(stderr, "%s\\n", message);
}

int main (int argc, const char *argv[]) {
   NSAutoreleasePool *pool = [[NSAutoreleasePool alloc] init];
   int exitCode;

   setbuf(stderr, NULL);
   _NSSetLogCStringFunction(_GarbageFreeLogCString);
   exitCode = WOApplicationMain(@"Application", argc, argv);
   [pool release];
   return exitCode;
}
```

Be aware that this code references private APIs; this is an **unsupported** workaround and users should use these instructions at their own risk. Apple will not guarantee or provide support for this procedure. In addition, this function does not contain any Windows I/O code and will not give any output if run from a DOS shell.

WebObjects: HP-UX Bug May Cause WebObjects Problems

A bug in an HP library may cause a variety of errors in applications running on HP-UX machines with PA2.0 CPUs. It can affect HP-UX applications built with or without WebObjects. A fix for this problem is available from HP. This document explains:

1. General information about the bug

2. How can I tell if a particular HP-UX machine has the bug?

3. How can I tell if a particular application may be affected by the bug?

4. How can I patch the bug?

5. How can I work around the bug?

6. Technical details

Along with this document, you should download the file **Register.tar**. This archive contains source for a small application that tests for the bug's presence and example files useful for working around the bug. This document assumes that you are using WebObjects 4. However, other WebObjects versions are susceptible to the bug and should be patched using the HP patch mentioned below.

This article has been archived and is no longer updated by Apple.

1. GENERAL INFORMATION ABOUT THE BUG

This bug happens only on Hewlett Packard PA2.0 CPUs. For these CPUs, HP's library **/usr/lib/libdce.sl** has a bug in which a particular function corrupts a floating-point register. The function is pthread_yield(), part of the 'pthreads' package. Keep in mind that even if your code does not directly call this function, both Apple's frameworks and third-party libraries (such as Sybase's client library) may call it and trigger the bug. HP concurs that this is a bug in their library, and have assigned it bug number JAGAB25393. A patch from HP is available; please see section 4, below, for details.

It's difficult to predict the possible effects of the bug, so please read the sections below that describe how to test your system. Problems observed so far include:

- applications suddenly slow to a crawl, and sometimes recover
- calculations produce incorrect results

Keep in mind that this bug could cause a variety of other symptoms, including sporadic ones.

2. HOW CAN I TELL IF A PARTICULAR HP-UX MACHINE HAS THE BUG?

To see if your system (your HP CPU plus libraries) has the bug, run a test application:

1. Download and unpack the **Register.tar** file from Apple's ftp site

2. Open a shell window

3. Type: `cd Register`

4. Type: `make`

   You can ignore the warnings from the compiler and linker

5. Type: `./Register`

   - If your system does **not** have the bug, the output from step 5 will be:
     10
     10
   - If your system **does** have the bug, the output will look like:
     10
     <some number other than 10>

We recommend that you use this test app instead of looking at the CPU model (because if you receive a new library in the future, having a PA2.0 CPU will no longer cause problems).

3. HOW CAN I TELL IF A PARTICULAR APPLICATION MAY BE AFFECTED BY THE BUG?

If the above test shows that your system does have the bug, you should assume that all your applications are affected, and apply the patch or

workaround described below to all applications. This will simplify your work, because it can be difficult to determine which applications are affected. The bug affects only applications that use HP's 'pthreads' package. This includes (at least) applications using 'cthreads' or Foundation's NSThread class, since both of those use 'pthreads'. Keep in mind that even though an application's code may not use threads directly, it may include libraries (such as Sybase's client library) that use threads. To see if your application uses threads, debug it under gdb, breakpoint in "pthread_create", and run the application.

If you **do** hit a breakpoint in "pthread_create", your application uses threads and risks encountering the bug. If you **don't** hit a breakpoint while running your application through typical operations, your application may not be at risk.

Example:

```
shell> gdb myApplication
GDB is free software and you are welcome to distribute copies of it
under certain conditions; type "show copying" to see the conditions.
There is absolutely no warranty for GDB; type "show warranty" for details.
GDB 4.15.3 (hppa1.1-hp-hpux10.10),
Copyright 1996 Free Software Foundation, Inc...
(gdb) break pthread_create
Breakpoint 1 at 0x5a58
(gdb) run
Starting program: /tmp_mnt/Net/custom/homes/ranch/morton/pthread
Breakpoint 1 at 0x7aa431f8
```

The following output reveals that your application uses threads, which tells you that it may encounter the bug.

```
Breakpoint 1, 0x7aa431f8 in pthread_create ()
(gdb) quit
The program is running. Quit anyway (and kill it)? (y or n) yes
```

4. HOW CAN I PATCH THE BUG?

HP has provided a patch for this problem. Apple recommends that all WebObjects users apply this patch. To get more information on the patch, point your Web browser to:

http://us-support.external.hp.com

If you don't have an account, click on the "New Users Register Now!" to start the registration process. Once you've logged in, click the "Individual Patches" link, then the "Retrieve a Specific Patch" link. The patch number for this patch is PHHS_16429. This will show a page that allows downloading the patch and also gives details as to which modules are affected. Complete installation instructions on the patch are available from the HP Web site.

The patch is about 28 MB. As with any patch, you should back up your system beforehand, and test everything afterwards.

After you install the patch, you do not need to reboot or rebuild applications affected by the register-trashing bug--your applications should begin to work immediately. (The patch also fixes some other things that **do** require a reboot, though.)

Apple recommends that all users install this HP patch. However, you should note this warning from HP's installation instructions:

IMPORTANT NOTE

> Oracle 7.3.3 and above will need to be relinked. This patch contains changes to the libcma library.
> Applications such as Oracle that use this library and are built static will need to be relinked.
> For information and help for the rebuild please contact your Oracle support personnel.

Because some users may not be able to install the patch, Apple also provides an alternate workaround for this bug in Section 5, below.

5. HOW CAN I WORK AROUND THE BUG?

Apple recommends that you install HP's patch, as described in section 4. However, if you are unable for some reason to install the patch, you can work around the bug by:

- Installing an alternate library which HP ships, but does not install by default.
- Changing either your application's makefiles or WebObjects' makefiles to link with this library

You do **not** need to change how you build frameworks or libraries. The only thing that matters is how you link when you build executable files (applications and tools).

Because the workaround involves linking with a static library instead of a dynamic library, there are two downsides to implementing the workaround in every application:

- Your applications will use more memory. This is especially important if you run multiple copies of your application--each instance will use more memory. When linked with the static library, an executable grows by about 3 MB on disk, so the memory used while running will probably grow by a similar amount.
- Your applications will not automatically incorporate changes that may appear in the shared library when you patch or upgrade HP-UX.

Despite these potential problems, we recommend that, when in doubt, you should add the workaround to all apps. Of course, using the HP patch is preferable to either.

The alternate library in question is:

```
/opt/dce/lib/libdce.a
```

You will need to use HP's installer software, /usr/sbin/swinstall, to install the software. Details of the installation will depend on your system and configuration.

Once the library is installed, you can modify selected applications to link with it by:

1. If the source directory does not have a Makefile.preamble file, create a Makefile.preamble containing this one line:

```
LOCAL_LDFLAGS += -L/opt/dce/lib -ldce
```

If you already have a Makefile.preamble, add the line above to the end of it (unless the file already has a line defining LOCAL_LDFLAGS, in which case you should add the options "-L/opt/dce/lib -ldce" to the end of that line).

2. "Make clean" your application (since the above change will not be enough to cause "make" to rebuild) and then "make".

Or you can modify two system-wide make files that WebObjects uses to build WO applications and tools. This saves you time, and makes sure no project slips through the cracks, but it may have downsides to this approach, as discussed above. To modify the two system-wide make files:

1. Log in as or su to root and cd to the **Register** directory

2. Type the following commands to create the local makefiles (if they don't already exist) and patch the makefiles:

```
mkdir -p /opt/Apple/Local/Developer/Makefiles/pb_makefiles
touch /opt/Apple/Local/Developer/Makefiles/pb_makefiles/tool.make.preamble
cp /opt/Apple/Developer/Makefiles/pb_makefiles/wo-preamble.make wo-preamble.make.bkp
cp /opt/Apple/Local/Developer/Makefiles/pb_makefiles/tool.make.preamble tool.make.preamble.bkp
cat preamble-additions >> /opt/Apple/Developer/Makefiles/pb_makefiles/wo-preamble.make
cat preamble-additions >> /opt/Apple/Local/Developer/Makefiles/pb_makefiles/tool.make.preamble
```

3. "Make clean" any application you need to rebuild (since the above change will not be enough to cause "make" to rebuild) and then "make".

Try rebuilding the Register application to make sure you've installed and linked to the new library correctly. After making the application, use the "chatr" command to examine the application's attributes:

```
chatr Register
```

If you see a line in the output that looks like:

dynamic /usr/lib/libdce.1

then the application is still using the old library. If this line does not appear, the application is using the new library. Since the new library is statically linked, no entry will appear for it.

6. TECHNICAL DETAILS

The bug is that, on PA2.0 CPUs, floating point register 12 ($fr12) is not preserved across calls to pthread_yield(). This violates the HPPA calling conventions. Many system calls use pthread_yield(), so they may also fail to preserve the register. This bug exists in the current release of the library /usr/lib/libdce.sl. The non-shared ("archive") version of this library (optionally installed in /opt/dcelib/libdce.a) does not have the bug. We have no reason to believe that the sharing itself causes the bug.

The bug typically affects compiled code which is optimized, since optimizations causes floating-point registers to store local variables or intermediate values. Because many compiler allocate registers in ascending order, the bug will often have no effect on a method or function that declares fewer than five local floating-point values.

In summary, the bug occurs when:

- Your application runs on HP-UX 10.xx system.
- Your machine has a PA2.0 CPU.

- Your application uses HP's 'pthreads' package.
- You have five (?) or more floating-point variables in a function/method.
- You ask the compiler to optimize (that is, variables go in registers).
- You make certain system calls at a time when variables are meaningful.

This bug can trash floating-point registers at various points in your code, Apple's frameworks, and third-party libraries. One affect it has on the Foundation framework is especially problematic: At the time that NSRunLoop fires an NSTimer, $fr12 contains the current real time. If the code invoked by a timer makes any of several system calls, NSRunLoop sees an incorrect time. It may conclude that other NSTImers are "way behind", and begin firing them madly to catch up. This can cause applications to perform very slowly, sometimes recovering later.

NeXTSTEP 3.3 Patch 2 Overview

This patch is now obsolete. Please see the NeXTSTEP Current Patch List, TIL article **70038**, for information on the most current patches for NeXTSTEP and Enterprise Objects Framework. This obsolete patch is provided here as a convenience to our customers who have not yet upgraded to the most current patch level.

This article has been archived and is no longer updated by Apple.
NeXTSTEP 3.3 Patch 2 supercedes NeXTSTEP 3.3 Patch 1, released in 1995. If you have already installed Patch 1 on your system, you can install Patch 2 over your existing installation. If you have not installed Patch 1, you do not need to. See **TIL article 72066** for details on NeXTSTEP 3.3 Patch 1.

NeXTSTEP 3.3 Patch 2 also supercedes the Foundation User Patch. Again, Patch 2 can be installed on a system with this patch previously installed. If you have not installed the Foundation User Patch, you do not need to. See **TIL article 72116** for details on the Foundation User Patch.

NeXTSTEP 3.3 Patch 2 comes in several packages, depending on the User platform version. For Intel and NeXT-branded Motorola hardware platforms, download the file **NS33CISCUserPatch2.tar**. For Solaris and HP-UX platforms, download the file **NS33RISCUserPatch2.tar**.

In addition, there is a NeXTSTEP 3.3 Patch 2 Developer package, **NS33DeveloperPatch2.tar**. This is a multi-architecture installer package, and should be installed on systems that have NeXTSTEP 3.3 Developer installed.

Important: If you are installing the Developer patch, please read section 6 of the release notes carefully. There are some manual steps you must take to prevent some Year 2000 issues.

If you use Enterprise Objects Framework on your system, it should be installed before you install NeXTSTEP 3.3 Patch 2. Patch 2 includes fixes in system components that were originally installed by either EOF or the Foundation User Patch.

The NeXTSTEP and EOF software packages should be installed in the following order:

- NeXTSTEP 3.3 User
- NeXTSTEP 3.3 Developer (optional)
- EOF 1.1 User (optional)
- EOF 1.1 Developer (optional)
- NeXTSTEP 3.3 Patch 2 User package
- NeXTSTEP 3.3 Patch 2 Developer package (optional)

After download, you may need to decompress the file with the command (example):

```
tar xf NS33CISCUserPatch2.tar
```

This will unpack the single "tar" file used for download into the .pkg format compound document used by the NeXTSTEP installer. Your Web browser or FTP client may perform this step for you.

To install NeXTSTEP 3.3 Patch 2, perform the following steps:

1. Log in as root on your NeXTSTEP system. If you're not sure how to log in as root, see your system administrator.
2. Double-click the **NS33CISCUserPatch2.pkg** (or **NS33RISCUserPatch2.pkg**) file icon.
3. Click the Install button in the Installer package window. An Install Package panel will open.
4. Click Install in the Install Package panel and, when prompted for confirmation, click OK to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.
5. If you do not need to install the Developer patch, skip to step 8 to complete the installation. To install NeXTSTEP 3.3 Developer Patch 2, double-click the **NS33DeveloperPatch2.pkg** file icon.
6. Click the Install button in the Installer package window. An Install Package panel will open.
7. Click Install in the Install Package panel and, when prompted for confirmation, click OK to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.
8. When the installation completes, the system must be rebooted. Log out and use the reboot button on the login panel.

EOF 1.x: Correcting Century Issues in the EOF Examples

Apple is not aware of any century problems with Enterprise Objects Framework versions 1.1 or 1.2 which would affect development or deployment of EOF applications. However, two scripts which install example data on Oracle for the Enterprise Objects Examples use a two-digit year format, which is not consistent with Apple's recommended date-handling practice. This article provides instructions on how to convert these example scripts to the preferred four-digit year format.

EOF uses many components of the underlying OPENSTEP or NeXTSTEP system. In order to ensure that EOF is year 2000 compliant, you must install the appropriate OPENSTEP, OPENSTEP Enterprise, NeXTSTEP, or PDO patch on your system, following the install order given in the patch overview document.

EOF 1.0 has not been tested for year 2000 problems; current EOF 1.0 users will be provided with an upgrade to EOF 1.1 at no charge. For more information, please see Apple Enterprise Software's Year 2000 page at http://www.apple.com/enterprise/y2k/. For year 2000 information on EOF 2.X, please see **TIL article 70085**.

For more information on Apple's Year 2000 program and the Year 2000 status of Apple software products, please visit the Year 2000 Information Page at http://www.apple.com/about/year2000/

This article has been archived and is no longer updated by Apple.
Two scripts which populate database tables for the People example use two-digit years in their date values. Customers can edit these scripts to use the four-digit year format which Oracle provides. The two problem scripts are "installPEOPLE.sqloracle6" and "installPEOPLE.sqloracle7" in /NextDeveloper/Examples/EnterpriseObjects/PeopleDBScripts.

In "installPEOPLE.sqloracle6", for all he insert statements into the EMPLOYEE table, change the two-digit year data to use a four-digit year. For example:

```
insert into EMPLOYEE values ( 101, 101, 'Winston', 'James', '415-323-7265', '6269 Washington Ave.',
'Woodside', 'CA', '94160', 1, ' 14-JAN-89', 101, 5700.00 );
```

should be changed to:

```
insert into EMPLOYEE values ( 101, 101, 'Winston', 'James', '415-323-7265', '6269 Washington Ave.',
'Woodside', 'CA', '94160', 1, ' 14-JAN-1989', 101, 5700.00 );
```

In "installPEOPLE.sqloracle7", for all the insert statements into the EMPLOYEE table, change the two-digit year data to use a four-digit year and change the date format to a four-digit year specifier. For example:

```
insert into EMPLOYEE values ( 101, 101, 'Winston', 'James', '415-323-7265', '6269 Washington Ave.',
'Woodside', 'CA', '94160', 1, TO_DATE(' 14-JAN-89', ' DD-MON-YY'),101, 5700.00 );
```

should be changed to:

```
insert into EMPLOYEE values ( 101, 101, 'Winston', 'James', '415-323-7265', '6269 Washington Ave.',
'Woodside', 'CA', '94160', 1, TO_DATE(' 14-JAN-1989', ' DD-MON-YYYY'),101, 5700.00 );
```

The scripts may be modified using any text editor, or by the use of 'sed', as demonstrated below. You must have the proper permissions to edit these files.

```
mv installPEOPLE.sqloracle6 installPEOPLE.sqloracle6.bak
sed 's/[0-9][0-9]\\-[A-Z][A-Z][A-Z]\\-/&19/g' installPEOPLE.sqloracle6 > installPEOPLE.sqloracle6

EOF 2.x: Correcting Century Issues in the EOF Examples

Apple is not aware of any century problems with Enterprise Objects Framework versions 2.1 or 2.2 which would affect development or deployment of EOF applications. However, two scripts which install example data on Oracle for the Enterprise Objects Examples use a two-digit year format, which is not consistent with Apple's recommended date-handling practice. This article provides instructions on how to convert these example scripts to the preferred four-digit year format.

EOF uses many components of the underlying OPENSTEP or NeXTSTEP system. In order to ensure that EOF is year 2000 compliant, you must install the appropriate OPENSTEP, OPENSTEP Enterprise, NeXTSTEP, or PDO patch on your system, following the install order given in the patch overview document.

EOF 2.0 has not been tested for year 2000 problems; current EOF 2.0 users will be provided with an upgrade to EOF 2.1 at no charge. For more information, please see Apple Enterprise Software's Year 2000 page at http://www.apple.com/enterprise/y2k/ For year 2000 information on EOF 1.X, please see **TIL article 70084**.

For more information on Apple's year 2000 program and the year 2000 status of Apple software products, please visit the Year 2000 Information Page at http://www.apple.com/about/year2000/

This article has been archived and is no longer updated by Apple.
The ModelerBundler example in the Enterprise Objects Examples on OpenStep 4.2 and OpenStep Enterprise 4.2 uses a two-digit year format for dates. The string is only used for display, not editing, so there is no problem with the function of the example. However, this is not prefered usage for Year 2000 compliant applications. The Apple reference number for this bug is 2341388.

Customers can edit the source for this example and rebuild it if a four-digit year format is desired. In $NEXT_ROOT/NextDeveloper/Examples/EnterpriseObjects/ModelerBundle/CustomeColumns.m, change the date format on line 67 from %y to %Y:

```
67c67
< formatter = [[NSDateFormatter alloc]
initWithDateFormat:@"%m/%d/%y: %H:%M" allowNaturalLanguage:NO];
---
> formatter = [[NSDateFormatter alloc]
initWithDateFormat:@"%m/%d/%Y: %H:%M" allowNaturalLanguage:NO];
```

Rebuild the example according to the instructions in the EnterpriseObjects directory.

WebObjects 4: Database Save Problem with Custom Data Types in Java

Custom Value Coding allows developers to create their own custom data types. These data types can then be assigned as an attribute's data type in an Enterprise Object (EO) and stored in the database like any other supported data type. General information about creating custom data types can be found in the EOF Developer's Guide, pp. 111-113. This article describes a problem that developers may encounter when using custom data types in Java.

This article has been archived and is no longer updated by Apple.

Currently, a straightforward application of custom data types as described in the Developer's Guide will have a problem when implemented in Java. Specifically, saving an Enterprise Object with a custom data type attribute to the database will result in a java,lang,CloneNotSupportedException. The solution is to implement your own clone() method in the custom data type's class. As with the java.lang.Object.clone() your method must return a new instance of the class. Any manipulation or selection of the custom data object can also be accomplished in the clone() method.

Internet Router and Novell Token Ring VAP Problem

I have been having issues with what looks like the Novell Token Ring VAP and the Apple Internet Router. The following is a description of the issue, the observations of the packet traffic by an engineer from Novell, and myself, with a shot at a conclusion. I know that the description of the packet traffic is meaningless without the actual trace data in front of you, but sending the trace data was impractical due to size (5MB). If you are interested in looking at the collected data, I can get it for you.

If there are known issues with the Internet Router that manifest themselves by the following description, I need to know as soon as possible.

Observations: The Router Issue

Our company is seeing a issue where our 286 server drops connections. Our printers fade in and out of the Chooser. Our mail servers appear and disappear. Our network is nearly unusable. In the office we visited, there is a main token ring with four routers. Two of those routers connect the main ring to smaller rings that contain users. One of those routers connects to a LocalTalk segment. The other router routes to an Ethernet that passes back to the company's enterprise-wide net, and contains some large servers.

In general, we are worried about users on the two smaller rings and the LocalTalk segment talking to servers on the main ring. There are no "users" on the main ring, just routers and servers. The two servers involved are called "who" and "who2". All of the routers involved are Apple Internet Routers, running on some fast II-class Macintoshes.

To look at this issue we attached two LANalyzers to the network, one (LA1) on one of the smaller rings, and one (LA2) on the main ring. On the smaller ring, we caught all traffic in and out of the router. On the main ring we caught all broadcast traffic, all traffic in and out of the "who" server, and all traffic in and out of that router. We told engineers to halt the LANalyzers whenever they had a report of a dropped connection, and we would look at the issue in the morning.

The next morning they had very few reports of the network failing. They had two traces for us. One was a failure on the subring we were watching. Two were failures from the LocalTalk segment, whose router we were not specifically watching. In the case of the failure on the subring, we were watching, the traffic on the main ring was so high that we couldn't get enough information about the history before the crash.

We did see that the server (who2) had sent an ASP close connection request to the workstation, and that the workstation had received it. The server issues a close connection usually only when there aren't enough ASP tickle packets to convince the server that the connection is still up. But we could not look far enough back in time to see the cause of this close.

We looked at one of the LocalTalk failure traces, expecting to find little of interest, because we weren't specifically targeting that router. However, the LANalyzer on the main ring told an interesting story. What follows is my interpretation of the trace, showing the important points. There is probably other information to be gleaned from the trace.

Packet #186 the first traffic between WHO and the LocalTalk connected router about the ASP connection in question (called 17103_air) was a tickle packet. Instead of sending the tickle directly over the Ethernet, the packet was sent to a different router (let's call it MYSTERY) on the ring, one that we couldn't identify. Time 7:43:31.

Packet #36517103_air starts sending AARP request broadcasts, looking for the WHO node. It sends one every 200 millisec, and about 3 millisec later the WHO server responds. It seems that the AARP responses are well formed, but 17103_air continues to rebroadcast. This continues for approximately 15 seconds, and during that time no traffic between 17103_air and WHO takes place. We see some, but not much, traffic between 17103_air and the other router we were monitoring. Time 7:43:42.

Packet #64017103_air stops sending AARP requests to WHO, and starts sending packets. Several retries of an ASP Request are sent, all within a second, and the server responds back to 17103_air correctly in each case. The connection will continue correctly for a while, with 17103_air sending directly to WHO and vice versa. Time 7:43:57

Packet #95317103_air sends and ASP Req packet to WHO, and WHO sends the response to a new and different Token Ring address (MYSTERY2). We don't see this node forward the packet, but 17103_air sends the ASP release directly to WHO, so the connection is still up, and the packet did get to the end Macintosh. The connection continues, with WHO sending most of its packets on this connection (destined eventually for 17103_air) to MYSTERY2.

Packet #1161 WHO sends its tickle packet to MYSTERY2 instead of 17103_air.

Packet #1387 WHO sends an ASP Response to MYSTERY (remember him?).

Packet #1843 17103_air starts sending AARP request packets, looking for node WHO. Like in the sequence starting in packet 356, AARP requests are sent every 200 microsec, and WHO responds correctly to each and every request. 17103_air continues to request. We see no further packets from 17103_air to WHO. WHO continues to send tickle packets destined for the end workstation, but sends them to all kinds of routers (MYSTERY, MYSTERY2). Time 7:45:20.

Packet #4516 WHO sends a close connection packet to the workstation through 17102_air (the router we were watching in the first place). 17103_air is still AARPing. Time 7:47:09.

Packet #5043 17103_air stops AARPing. It does not send any further packets to WHO. The connection is dead. Time 7:47:26.

Questions and Issues

The first and most interesting question is why does the Apple Internet Router continue to AARP over and over again? Another question is, why did it stop AARPing in the first case, in so little time as to let the connection stay alive? Looking at the trace we see another router, 17102_air, AARP over and over again for the server WHO2.

This is obviously not an isolated issue, and it is the cause of the destruction of the connections. Possibly, it also backs up the router queues, and thus prevents NBP lookups, accounting for our NBP issues. The router statistics are showing a large number of "overflows" whatever that is.

The second question is why the 286 VAPs start sending to other routers besides the correct router (MYSTERY, MYSTERY2). Secondly, the VAPs do not seem to redirect back to the correct router after getting a packet from it. However, although "Inside AppleTalk" suggests the caching of routers and building up of a RTMP table via the RTMP stub, nothing particularly bad will happen except loss of bandwidth and overburdening of routers.

In conclusion, the company's issue is a sporadic loss of routing through our Apple Internet Routers, caused by an illegal activity of the AIRs (not accepting AARP responses correctly). The cause of this failure remains unknown.

The central issue is that printers, file servers, and mail servers drop in and out of the Chooser. This brings up a couple of questions. How many of each type of device do you have in each zone? Could you do an Inter*Poll of the affected zones for each type of device in question and send us the information? Here is some information and a possible answer:

This is how the Chooser really works in a nutshell:

The Chooser sends out a Name Binding Protocol (NBP) packet looking for all devices of type XXXXXX (for example, type LaserWriter). It sets up a buffer of 512 bytes for the responses. The responses look like:

```
device name length      1 byte
device name           variable bytes    e.g. MyLaser-Hands off
type name length       1 byte
type name             variable bytes    e.g. LaserWriter
zone field length      1 byte
zone name field       variable bytes    probably *
```

The Chooser gets such a packet back for each device, i.e., each LaserWriter. When the 512-byte buffer is full of these packets, it stops looking for device names to display. This means that some LaserWriters might not be displayed immediately. If you leave the Chooser window open, however, the Chooser continues to send out NBP lookups every 1.47 seconds. Different LaserWriters could respond more quickly each time. In this case, you may see the Chooser show and hide various devices.

This means that the number of devices the Chooser can show really depends on how long the type name (like "LaserWriter") is and how long the device names are.

The number 18 is an average number, based on device names being about 13- or 14 characters long and the device name being about 10 or 11 characters long.

In System 7.0, the buffer size for the Chooser is increased to 1024. This means, on an average, about 36 devices will be able to be displayed.

There is a way to affect the manner in which the lookup is done, which could help in some environments, especially in wide-area-network environments where slow data links may be used. If you modify the GNRL resource in the Chooser document (AppleShare, for example), it will affect every NBP lookup that is done from the Chooser for that type of device.

The Chooser uses these values to determine the NBP lookup interval and retry values for the current NBP transaction. The default of 0705 tells the Chooser to send five NBP lookup requests at an interval of 7/8ths of a second. This process is repeated in an infinite loop, until the user closes the Chooser.

Chooser Event Flow Example:

User opens Chooser and selects the AppleShare CDEV
GNRL resource -4096 loaded value = (5002)
NBP lookup mechanism started

NBP Loop:
Get NBP ID for this transaction
(Note: All NBP request and replies for this loop will use this ID)

Send first lookup (NBP ID = "New")
Collect and display responses from the NBP lookup ID "New"
Wait 10.6 seconds

Send second lookup (NBP ID still = "New")
Collect and display responses from the NBP lookup ID "New"
Wait 10.6 seconds

Discard all buffers and data associated with NBP ID "New"
(Note: If a response is received for NBP lookup ID =
"New" after this point the reply data would be discarded
and the device would not be added to the list in the Chooser)
Do some other misc. cleanup (approx. time 1 sec)

goto NBP Loop

End NBP Loop:

With the retry timer set to such a large value the multiple retry count is really not necessary. On the other hand, it doesn't hurt either, and it effectively increases the time we'll wait for NBP replies to over 20 seconds for the current transaction. The idea behind the retry count is to send several lookup requests out in quick succession (default < 1 sec.), in case there are devices which were unable to respond because they were busy or because the previous packet never reached them.

The reason that increasing the interval timer helps in the case of remote servers is directly tied to the way the NBP mechanism works. The Chooser maintains only 1 NBP lookup request at a time, tracking all replies to that request by way of the NBP ID mechanism. Replies that are received that do not match the current request ID are discarded.

The request ID is maintained only for the current NBP request, the interval and retry counters for this request can be tuned via the GNRL resource. In other words, if you set the retry counter to 10 and the interval timer to 50 the NBP ID would be maintained for 10 requests at an interval of 10.6 seconds. The GNRL resource is documented in "Inside Macintosh, Vol. 4", page 216.

AARP Issue

The symptoms you describe with the Apple Internet router AARPing for the same node over and over is probably attributed to the router being overloaded and not able to accept the response AARPs. You mention that the router is getting a fair amount of overflow errors, this would lead me to believe that the routers are indeed overloaded.

What ports on the routers are getting the overflow errors and how many are reported over the course of a day, a week? Overflow errors are caused by the router being too busy to process all incoming packets on an interface. The network interface chip set can detect that a packet was available but that the processor was too busy to get the packet from the interface before the next packet arrived. There may be some other issues related to your environment, but this is a good starting point.

Novell VAPs Sending to Random Routers

AppleTalk Phase 2 does provide an enhancement that lets your node cache network to router pairs for use when determining where to route a packet destined for a remote network. When the AppleTalk protocol DDP receives a packet from a remote network, it strips off the data-link source address of the packet. This is the address of the last router on the route from the original network. This router should generally be the optimal router in
terms of hop count back to the original network. You can then use that router for any future transactions to that network.

Now that I've explained all of that, you're saying, "Okay, that sounds right, but the Novell server is not doing what it's supposed to." The real story is that this enhancement is an optional, implementation-specific addition that is not required by the AppleTalk protocol. In this case, it would be normal for the Novell server to act the way that you described, if they did not implement the "Best Router" enhancement.

Conclusions

We first need to get a handle on the environment that you have, including numbers of devices per network and per zone. We need to take a close look at the statistics from the Apple Internet routers, average load on the various network segments as measured by the Internet Router, as measured by a network monitor/analyzer.

A close look at traffic patterns could also be helpful in determining where to best segment the network if it becomes necessary. It may be that the

traffic on the main ring is so heavy that the Macintosh routers can't keep up. We don't really have any statistical, benchmark, or historic information that would tell us when the use of an AIR on a token ring is not going to offer the best performance. At this point, we just need to collect all the information and then take it one step at a time.

The LANalyzer traces wouldn't do us any good, because we have a Network General Sniffer. If we really need to see some trace data, we'll do some tests using a Sniffer on your end, or the LANalyzer data could be saved to an ASCII file and shipped to us on a tape. I don't think we need to worry about the trace data yet.

OPENSTEP 4.2 Patch 4 Overview

This document contains an overview and download information for Apple's Patch 4 for OPENSTEP 4.2 for Mach and OPENSTEP Enterprise 4.2. This patch set includes fixes that address the Year 2000 compliance issue (century rollover). Apple recommends that all users of OPENSTEP 4.2 install this patch set. Detailed release notes, including specific problems fixed with Apple bug tracking numbers, are included in the download package. Please read these release notes for important information on what is and is not covered by this patch.

Users of OPENSTEP versions prior to release 4.2 should register for and install an upgrade from Apple to OPENSTEP 4.2 before installing this patch. For more information, please see Apple Enterprise Software's Year 2000 page at http://www.apple.com/enterprise/y2k/.

OPENSTEP 4.2 Patch 4 supercedes all previous OPENSTEP general system patches. If you have already installed an OPENSTEP patch on your system, you can install Patch 4 over your existing installation. If you have not installed any previous patches, you do not need to.

For additional Year 2000 tips for OPENSTEP developers, see **document 70125**.

The OPENSTEP Current Patch List, **document 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read this document if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.
OPENSTEP 4.2 Patch 4 Release Notes:

- Download **OS42Patch4ReleaseNotes.pdf**.

OPENSTEP 4.2 User Patch 4 comes in four packages:

- For OPENSTEP for Mach installations, download **OS42MachUserPatch4.tar**.
- For Windows NT installations, download **OS42_NT_User_Patch4.exe**.
- For Solaris installations, download **OS42_Solaris_Patch4.tar.Z**.
- For HP-UX installations, download **OS42_HPUX_Patch4.tar.Z**.

OPENSTEP 4.2 Developer Patch 4 comes in two packages:

- For OPENSTEP for Mach installations, download **OS42MachDevPatch4.tar**.
- For Windows NT installations, download **OS42_NT_Dev_Patch4.exe**.

Download and install these packages if you use the OPENSTEP development tools on your system. IMPORTANT: If you are installing the Developer patch, please read section 6 of the release notes carefully. There are some manual steps you must take to prevent some Year 2000 issues.

If you use Enterprise Objects Framework on your system, it should be installed before you install OPENSTEP 4.2 Patch 4. Patch 4 includes fixes in system components that were originally installed by EOF. The OPENSTEP and EOF software packages should be installed in the following order:

- OPENSTEP 4.2 User
- OPENSTEP 4.2 Developer (optional)
- EOF User (optional)
- EOF Developer (optional)
- OPENSTEP 4.2 Patch 4 User package
- OPENSTEP 4.2 Patch 4 Developer package (optional)

Installation instructions - OPENSTEP for Mach

To install OPENSTEP 4.2 for Mach Patch 4 on an OPENSTEP for Mach system, perform the following steps:

1. If you downloaded OPENSTEP 4.2 for Mach Patch 4 from the internet, you may need to decompress the file with the command (example):

tar xf OS42MachUserPatch4.tar

This will unpack the single 'tar' file used for download into the .pkg format compound document used by the OPENSTEP for Mach installer. Your web browser or FTP client may perform this step for you.

2. Log in as root on your OPENSTEP system. If you're not sure how to log in as root, see your system administrator.

3. Double-click on the OS42MachUserPatch4.pkg file.

4. Click the Install button in the Installer package window. An Install Package panel will open.

5. Make sure that there are no other OPENSTEP or EOF applications running.

6. Click 'Install' in the Install Package panel and, when prompted for confirmation, click OK to proceed. The Installer window displays information about the progress of the installation, which may take several minutes. If you do not need to install the Developer patch, skip to step 10 to complete the installation.

7. To install OPENSTEP 4.2 Developer Patch 4, double-click on the OS42MachDevPatch4.pkg file.

8. Click the Install button in the Installer package window. An Install Package panel will open.

9. Click 'Install' in the Install Package panel and, when prompted for confirmation, click OK to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.

10. When the installation completes, the system must be rebooted. Log out and use the reboot button on the login panel.

Installation instructions - OPENSTEP Enterprise for Windows NT

To install OPENSTEP 4.2 Patch 4 on a Windows NT 4 system, perform the following steps:

1. If you downloaded OPENSTEP 4.2 Patch 4 from the internet, run the OS42_NT_User_Patch4.exe file to uncompress the patch installer, OS42UserPatch4Intstaller.exe and the release notes.

2. Read the release note distributed with this patch.

3. Log in as a user with Administrator privileges.

4. Make sure that there are no OPENSTEP or EOF applications running.

5. Double-click on the OS42UserPatch4Intstaller.exe file to start the install process.

6. A screen will appear with some information about this patch. After you have read it, click "Next" to continue.

7. The license agreement for this patch will appear. To agree to the license and continue the installation, click "Yes".

8. The patch will now be installed on your system and you will be asked if you want to reboot. If you have OPENSTEP Enterprise 4.2 Developer installed on your system, select "No, I will restart my computer later" and repeat steps one through seven using the Developer patch installer, OS42NTDevPatch4Installer.exe. Otherwise, proceed to step nine.

9. Select "Yes, I want to restart my computer now" to reboot your Windows NT system. The WinZip self-extractor will automatically quit and remove the temporary installation in about 20 seconds.

Installation instructions - OPENSTEP Enterprise for Solaris and HP-UX

To install OPENSTEP 4.2 Patch 4 on a Solaris or HP-UX system, perform the following steps:

1. Download the compressed tar file for your platform by clicking the appropriate link above.

2. Also **download** the installer script, "patcher.sh".

3. Log in as root. If you're not sure how to log in as root, see your system administrator.

4. Make sure that there are no OPENSTEP or EOF applications running.

5. Change to the directory containing the patch and the patch installer, "patcher.sh".

6. At a shell prompt, type:

patcher.sh -install OS42_Solaris_Patch4.tar.Z

or

patcher.sh -install OS42_HPUX_Patch4.tar.Z

For more information on using the "patcher.sh" program, type the following at the command prompt:

patcher.sh -help

7. Reboot your Unix system

WebObjects 4: Using Oracle 8i (Oracle 8.1.5) with WebObjects

This article discusses the symptoms and solutions for two problems some WebObjects 4 developers may encounter with Oracle 8.1.5, also known as Oracle 8i.
This article has been archived and is no longer updated by Apple.
Question 1: I'm using WebObjects 4 to connect to an Oracle 8.1.5 or Oracle 8i database on Windows NT. Although SQL*Plus has no problems, EOModeler can't see the database and my application can't connect at runtime; it appears that I am using an invalid SID.

Answer: A registry entry required by EOF is not created during the Oracle 8.1.5 installation procedure. In the Windows NT registry, make sure that under:

\\HKEY_LOCAL_MACHINE\\SOFTWARE\\ORACLE

the key

ORACLE_HOME

exists and has the string value of:

C:\\Oracle\\Ora81

replacing "C:\\Oracle\\Ora81" with the correct path to your Oracle install directory.

Question 2: I'm using WebObjects 4 to connect to an Oracle 8.1.5 or Oracle 8i database on Solaris. My WebObjects applications won't compile or don't seem to be able to access the database.

Answer: When compiling a WebObjects application using Oracle 8.1.5 or Oracle 8i database for Solaris, you must add the following entry to OTHER_LIBS in your Makefile.preamble::

-L$(ORACLE_HOME)/lib -lclntsh -lcommon8 -lcore8 -lnls8

Also, keep this line COMMENTED in your Makefile.preamble:

#include $(MAKEFILEDIR)/pdo-eoadaptor-linking.make

Your application should now compile and run correctly against Oracle 8.1.5.

WebObjects: Incorrect Time Values for GMT under Windows NT 4.0 SP4

Some changes in the way Windows NT handles time zones were made between Windows NT 4 Service Pack 3 and Service Pack 4. As a result, some Foundation time and date methods will display the wrong time when the time zone is set to GMT on a Service Pack 4 system. To correct the problem, you will need to make some changes to the WindowsName.table file on these systems. This document contains instructions on making the necessary changes.
This article has been archived and is no longer updated by Apple.

Modifying the WindowsName.table file under WebObjects 4

The WindowsName.table file is found in your WebObjects Frameworks directory, under:

```
Foundation.framework/Resources/TimeZoneInfo/WindowsName.table
```

This file is a serialized plist, so you will need to deserialize it before editing. To preserve the Unicode file format, only use TextEdit to modify this file.

1. In a Bourne shell, change to the directory containing the WindowsName.table file and enter the following commands:

```
cp WindowsName.table WindowsName.table.orig
pl -input WindowsName.table > MyWorkFile
rm WindowsName.table
```

2. Next, use TextEdit to change the following lines in **MyWorkFile**:

- Change **"GMT Normalzeit" = Africa/Casablanca;** to **"GMT Normalzeit" = Europe/London;**
- Change **"GMT Standard Time" = Africa/Casablanca;** to **"GMT Standard Time" = Europe/London;**
- Change **"GMT \\U6a19\\U6e96\\U6642" = Africa/Casablanca;** to **"GMT \\U6a19\\U6e96\\U6642" = Europe/London;**

3. Finally, use the following commands to reserialize the file:

```
pl -output WindowsName.table < MyWorkFile
rm MyWorkFile
```

Modifying the WindowsName.table file under OPENSTEP Enterprise 4.2

The steps needed to modify the file are the same as for WebObjects, except that you do not need to serialize or reserialize the file. Using TextEdit, make the changes to the WindowsName.table file listed under Step 2 for WebObjects, above. Apple recommends that you make these changes on a copy of the file rather than the original file; however, you do not need to use the 'pl' command to deserialize and reserialize the copy first. To preserve the Unicode file format, only use TextEdit to modify this file.

WebObjects 4: Application Timeout Reveals Server for Virtual Domain Systems

Q: I'm using WebObjects 4 on a system using virtual domains; a server named "ecom3.apple.com" might handle requests directed to "store.webobjects.com". However, when I schedule one of my application instances to start refusing new requests and a session is redirected to another server, for the rest of the session the actual server name (for example, "ecom3.apple.com") appears in the URL instead of my virtual domain name. How can I stop this from happening?
This article has been archived and is no longer updated by Apple.
A: This problem occurs because WebObjects applications use HTTP 301 messages to redirect sessions when they are set to refuse new requests. The web browser then detects the actual hostname of the new server based on the partial URL returned by WebObjects.

You can work around this problem by having WebObjects return a full URL in this instance instead of a partial one. This requires overriding a private method in WOApplication. The method is **-_newLocationForRequest:**, and the new version should return the URL that the redirect will use. Your code might look like this:

```
- (NSString*)_newLocationForRequest:(WORequest*)aRequest {
 NSString* aNewURL = [NSString stringWithFormat:@"http://store.webobjects.com/%@/%@", [aRequest
adaptorPrefix], [aRequest applicationName]];
 return aNewURL;
}
```

WebObjects 3.1 Patch 1 Overview

This document contains an overview and download information for Apple's Patch 1 for WebObjects 3.1. This patch set includes fixes that address the Year 2000 compliance issue (century rollover). Apple recommends that all users of WebObjects 3.1 install this patch set. Detailed release notes, including specific problems fixed with Apple bug tracking numbers, are included in the download package. Please read these release notes for important information on what is and is not covered by this patch.

Users of WebObjects versions prior to release 3.1 should register for and install an upgrade from Apple to WebObjects 3.1 before installing this patch. For more information, please see Apple Enterprise Software's Year 2000 page at http://www.apple.com/enterprise/y2k/.

For additional Year 2000 tips for WebObjects developers, see **TIL article 70048**.

The WebObjects Current Patch List, **TIL article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. Please read this document if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.

Introduction

This document describes Apple's Patch 1 for WebObjects 3.1. This patch set includes fixes that address the Year 2000 compliance issue (century rollover). Apple recommends that all users of WebObjects 3.1 install this patch set. These Release Notes also document the issues found in Enterprise Objects Framework (EOF).

How To Use

This patch consists of patch binaries for **Solaris**, **Windows NT**, and **HP-UX** platforms. The **release notes** included with the patch contain descriptions of additional steps required for full compliance on developer installations for all platforms. A separate **patch installation script** is also required for Solaris and HP-UX users.

This patch affects the development and deployment versions of WebObjects 3.1 on Windows NT, Solaris, and HP-UX. No WebObjects patch is required for users of WebObjects 3.1 on OPENSTEP 4.2 for Mach; however, you must have OPENSTEP 4.2 for Mach Patch 4 or later installed on your OPENSTEP system. WebObjects users on OPENSTEP for Mach should also read sections 3 and 4 of the **patch release notes**; these sections describe some manual steps you should take to avoid some Year 2000-related problems.

Apple has tested WebObjects 3.1 with Patch 1 installed and has determined based on the results that the software meets Apple's standard of Year 2000 compliance. For Apple, Year 2000 compliance means that the software does not produce errors processing date data in connection with the year change from December 31, 1999 to January 1, 2000, when using accurate date data in accordance with its documentation, provided all other products used with it properly exchange date data with the Enterprise Software product.. This includes the use of the database adaptors included with EOF, when used through EOF. It has been determined that the direct use of client library API, custom SQL statements, or other use of the database adaptors or software other than through the EOF APIs may produce results that do not meet Apple's standard of Year 2000 compliance.

What Is Not Covered

Third Party Software Applications

WebObjects 3.1 is designed to support certain third-party products, including but not limited to databases, web servers and HTML editors. Apple has not tested the Year 2000 status of these products and will not guarantee or provide support for them.

Operating System Software

WebObjects 3.1 can be used under OPENSTEP for Mach, Windows NT, Solaris, and HP-UX. Because WebObjects depends on the underlying operating system for some time and date information, Apple cannot guarantee the operation of WebObjects after December 31, 1999 unless the underlying operating system is free of Year 2000 problems. Please contact your operating system vendor regarding the Year 2000 status of your system. WebObjects installations running on OPENSTEP 4.2 for Mach systems must have OPENSTEP 4.2 for Mach Patch 4 or a later patch version installed on their system for Year 2000 compliance.

Pascal: Turtlegraphics -- Circles

This article has been archived and is no longer updated by Apple.
The program below is supposed to draw a circle, but it doesn't--it draws an octogon. The drawing routines can calculate exactly where the end of the line will be, but with a move of only one dot, the result is limited to one of the eight adjacent dots. For example, if we move a distance of one dot at an angle of five degrees, then the co-ordinates of the destination are X + 0.09, Y + 0.99, which are rounded to X + 0, Y + 1.

Calculated Angle Actual Angle
0 - 22.5 0
22.5 - 67.5 45
67.5 - 112.5 90
112.5 - 157.5 135
157.5 - 202.5 180
202.5 - 247.5 225
247.5 - 292.5 270
292.5 - 337.5 315
337.5 - 382.5 0

The next table gives the calculated and actual X and Y coordinates for an angle of 5 degrees and varying move distances.

X-Coordinate Y-Coordinate
Move Calc Act Calc Act
1 0.09 0 0.99 1
2 0.17 0 1.99 2
3 0.26 0 2.98 3
4 0.35 0 3.98 4
5 0.43 0 4.98 5
6 0.52 1 5.97 6

The next diagram simulates the High-Res graphics display. Clearly, you must move at least 6 units for 5 degrees to show any effect.

As you can see, the computer can't display a 5 degree change unless the move is at least 6 units.

WebObjects: Crash in _doprnt() on Solaris 2.x

A bug in Solaris 2.x can cause WebObjects applications to crash under certain circumstances. This could affect any version of Portable Distributed Objects (PDO) or WebObjects 4.5.1 or earlier on Solaris. This document describes the problem and provides a patch WebObjects customers can use to avoid it on Solaris 2.5, 2.6, or 7.
This article has been archived and is no longer updated by Apple.

Problem description

A Sun/Solaris bug in the function _doprnt() can cause a WebObjects application to crash if it passes a NULL string argument to printf() or NSLog(), or if any Apple framework is passing a NULL string argument to printf(). This is caused by a bug in the implementation of the _doprnt() function in the Solaris C library and does not occur on other platforms (MacOS X Server, Windows NT, and HP-UX). The Solaris _doprnt() function does not check whether the argument is NULL and causes a segmentation fault when receiving a NULL string. This bug has been assigned Apple bug number 2388853.

If a crash was caused by this bug, the backtrace will normally look something like this:

```
Program received signal SIGSEGV, Segmentation fault.
0xee624614 in strlen ()
(gdb) bt
#0  0xee624614 in strlen ()
#1  0xee65a4ac in _doprnt ()
#2  0xee663514 in _fprintf ()
#3  0xef4fc33c in global constructors keyed to WOStaticURLUtilities.m ()
#4  0xef4fb080 in global constructors keyed to
WOStaticURLUtilities.m ()
#5 0xef4f80d0 in global constructors keyed to
 _OBJC_METACLASS_WOResponseContentDataFault ()
#6  0xef4ffc78 in global constructors keyed to
_OBJC_METACLASS_WOSessionStore ()
```

Testing for the bug

To determine if your Solaris machine has the bug, you can run the following simple test program:

```
/* This is test.c */
#include <stdio.h>
main()
{
       printf("%s", NULL);
}
```

After compiling the test program, run and see if it crashes with a SIGSEGV. Run it again under gdb, and check if the backtrace looks similar to the one described above. So far, we have seen this bug on Solaris 2.5, 2.6, 7, and Solaris 8.

The patch

If you are using PDO or WebObjects 2.x to 4.x on Solaris 2.5, 2.6, or 7, you can download the patch from Apple's FTP site. The patch is built as a .o file for the SPARC-Solaris platform. It provides a new implementation of _doprnt(), which is robust against NULLs. This patch does not work on Solaris 8.

FTP:

ftp://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/webobjects/patches/4.0.1/prntpatch.o

HTTP:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/webobjects/patches/4.0.1/prntpatch.o

To test the patch, recompile your test program and link it with the patch as follows:

```
gcc -o fixedtest test.c prntpatch.o
```

Rerun the test described above to confirm that the problem has been solved.

Using the patch in your project

Copy the patch file prntpatch.o into your project folder, and edit Makefile.preamble to include the patch at link time with the line:

```
OTHER_OFILES=prntpatch.o
```

As a safety measure, you may need to repeat this step for any custom-written frameworks that you are linking your application against.

Note: It is not necessary to include the patch file in the subprojects, if any, of your WebObjects application.

Disclaimers: There is no guarantee that this patch truly fixes the root of your problem. Even if the crash does not recur, you should still investigate whether your code is calling into a C string function with a NULL argument. Otherwise, your application may still generate exceptions even though this particular crashing problem is resolved.

This patch does not work on Solaris 8. (Although Apple has not qualified WebObjects 4.x on Solaris 8, most of WebObjects 4.x appears to work on Solaris 8; this patch is an exception.)

WebObjects 4: WOAssociationTiming Framework Example

The `WOAssociationTiming Framework` Example allows users to perform timing for the different phases of the request/response loop, such as in `takeValuesFromRequest:` or `invokeActionForRequest:`. This can aid WebObject users in performance tuning their applications. For more information on the applications of this example and performance tuning in general, see Knowledge Base Document 70102 "**WebObjects 4: Performance Tips**".
This article has been archived and is no longer updated by Apple.

Where to Find the Example

Download the WOAssociationTiming Framework from Apple's software update servers.

Building the Example

To add the timing framework to your web application, use Project Builder to add the framework to your PB.project, then add the following line in your _main.m file:

```
[WXSession poseAsClass:[WOSession class]];
```

Using the Example

To view the Timing Control page, access it via a URL such as:

`http://myhost:aPort/cgi-bin/WebObjects/MyApp.woa/wa/timingControl`

Please see the README file distributed with this framework for more information.

IIGS: "Visit Monitor" 03 Same as Released Version

Is there a difference between the Apple IIGS (ROM 03) I own, and other Apple IIGS systems with ROM version 03? My 03 is one of the first few hundred that were accidentally assembled with "Memory Peeker" and "Visit Monitor" stuck in the Classic Desk Accessories menu.

Anyway, I've documented a list of things that seem to be wrong with my ROM 03 Apple IIGS. Could you try out the things on the list with your ROM 03 (one without "Memory Peeker" and "Visit Monitor" in the CDA menu), and let me know if any of those things happen on your Apple IIGS.

The System Monitor

After entering Monitor with a "CALL-151" command or accessing it through "Visit Monitor/CDA", the system will freeze after entering the "LIST" command. Pressing any key after this causes a continuous scroll of inverse text, while the Error bell rings non-stop. Strangely enough, pressing certain keys will display different graphic modes while this is happening, replacing the scrolling text, but with the error bell still ringing, and no way to stop it.

Applesoft BASIC

When trying to run any program written in Applesoft BASIC that launches GS-specific programs (i.e., doing calls to Apple IIGS ROMs or hardware), the program will not run and gives this error message:

?SYNTAX ERROR IN 65182

All programs give the same error message. After this error message occurs from trying to load an Applesoft BASIC program, the GS/OS operating system won't run. Trying to load any disk that uses GS/OS to boot up will crash after the "Welcome to the Apple IIGS" message appears and gives the following error message:

Error Loading Apple IIGS.OS File. Error=$002E

After this you must turn the computer off for 30 seconds or more before you can load GS/OS without getting the same error message.

MDIdeas Card

When plugged into my ROM 03 Apple IIGS, the Stereo/Digitizer card from MDIdeas, does not function properly. Any sound that's recorded with the card is played back with an echo, and is noisy and scratchy (incompatible with either card or software). The card and software are not at fault, because they work perfectly on my other Apple IIGS, which is a ROM 01.

Software

Many software applications will not run on my Apple IIGS with the 03 ROMs, while they apparently run on other 03 ROM-d systems. (This includes public-domain and commercial software titles.)

RAM Disk

With 2.125MB in my Apple IIGS, there's a maximum RAM disk size of 1,920K. The system will not auto-format a RAM disk larger than 1,888K in size.

Selecting 1,920K from Control Panel won't auto-format.

* Each time you reset the computer to auto-format a RAM disk, the system freezes for 5 or more seconds.

* When a RAM disk is created, the system will erase the entire RAM disk after using Open-Apple Reset command a couple of times. (It seems to change the setting in the Control Panel to "Resize after reset: YES", thereby changing the setting by itself.)

Disk Access Slows Down

When loading up some GS-specific programs that use ProDOS 8 or ProDOS 16 as a launcher, the computer seems to have trouble loading ProDOS, and then trouble loading the main program system file. The program will take two to three times longer to start up than it will on a ROM 01-GS or other ROM 03-GS systems. It slows down so much that it appears the disk is damaged or corrupted. Some examples of programs that have this problem are "Diversi-Tune" and "Tunnel of Armageddon".

This article has been archived and is no longer updated by Apple.
Most of these problems can be avoided. The ROMs (early and late) are identical. Some systems went out configured improperly. Anyway, I'll take them one at a time.

System Monitor

"LIST" is not a Monitor command. To list the contents of memory locations, you only need to type "l" or "L". When the monitor sees "LIST" it scrolls 20 lines of location contents and then sets the display to inverse. The monitor queues commands typed as a string; the second command in the string is "i"; the command for inverse. "S" and "T" are not Monitor commands and seem to confuse the system. Typing "l", a carriage return, "i" and a carriage return works fine. You should read the "Apple IIGS Firmware Reference" for a complete description of the Monitor and its commands.

Applesoft BASIC

Without an exact description of the steps required to create the problem described, we can only speculate as to the cause of the problem.

It sounds as if you are trying to run a ProDOS-16 application from ProDOS-8. Whatever the case, some memory locations are being stomped on, seriously scrambling memory, because the system thinks a disk has been switched. If this continues to be a problem, let us know exactly what you are doing to cause this crash, and we'll dig into it.

MDIdeas Card

The MDIdeas card was developed for the original Apple IIGS. The company is now out of business and has therefore not upgraded the product to work with the new ROMs. The card (or perhaps the accompanying software) is not compatible with the new version of the ROMs. Applied Engineering offers a comparable product that is compatible with the new ROMs.

Software

We will need concrete examples of the differences when software is run on two different systems, because the ROMs are identical. The problems exhibited here may be a result of a drive problem (discussed in the "slows down" section below).

RAM Disk

It sounds as if you are using the Classic Control Panel to modify the RAM disk. The Classic Control Panel is not aware of the memory requirements of GS/OS and will let the user set unreasonable RAM disk sizes. GS/OS will re-assign the value as it "takes" memory back at boot time. Using the Graphic Control Panel will eliminate this problem. This is not a bug, because the Classic Control Panel is necessary when using the system with ProDOS-8.

As a side note, pressing Open-Apple-Reset is not a very elegant way to re-start the system. We highly recommend the use of menu-bar selections over this method. Use Open-Apple-Reset only as a last-ditch effort.

Disk Access Slows Down

The slowdown your customer is experiencing could be a result of copy-protected software. If other Apple IIGS systems with the same ROMs (03) load the software more quickly, swap in a disk drive from one of the other systems. It's possible that the drive is in need of cleaning, and has troubles reading copy-protected disks.

Again, the ROMs you received are the same as the ROMs shipped in later systems.

WebObjects 4: Creating a Java Tool Project

A tool is typically a GUI-less application, run from the command line, that is focused on one or just a few tasks. There are a few tricks to creating a Java tool project in Project Builder; this document helps you through the process.
This article has been archived and is no longer updated by Apple.
First, create your project as a WebObjects Application project type. This insures that all the required Java support is built into the project. The only frameworks that are required are the Foundation.framework and the JavaVM.framework. The only source that is required is the myWOApp_main.m file and two Java classes. Remove all other frameworks and classes not required for your project.

Then set up the myWOApp_main.m file to initialize the Java virtual machine and instantiate a Java class. Here is the standard implementation:

```
#import <JavaVM/NSJavaVirtualMachine.h>
int main(int argc, const char *argv[])
{
   NSAutoreleasePool * pool = [[NSAutoreleasePool alloc] init];
   Class JavaToolClass;
   id javaToolObject;
    // required for Solaris only to notify cthreads layer the main thread is being created
#if defined(__svr4__)
    unsigned long java_reserved[16];
    void cthread_set_java_vm_stack_base(void *);
    cthread_set_java_vm_stack_base(java_reserved);
#endif
   [NSBundle mainBundle];  //this initializes the JVM
   JavaToolClass = NSClassFromString(@"Tool");
   javaToolObject = [[JavaToolClass alloc] init];
   NSLog (@"Java Tool Object = %@",javaToolObject);
   [pool release];
   exit(0);       // insure the process exit status is 0
   return 0;      // ...and make main fit the ANSI spec.
}
```

The Java class Tool.java has been created. In this approach, Tool.java consists only of a constructor that instantiates another Java class, ToolImplementer.java here, which does the real work of this tool. After a ToolImplementer object is instantiated, execute one of its methods to start the tool working:

```
import java.lang.*;
public class Tool extends Object {
  public Tool() {
       super();
       System.out.println("Creating a Tool instance");
       ToolImplementer toolImplementer = new ToolImplementer();
       toolImplementer.executeSomething();
       System.out.println("toolImplementer.executeSomething() is executed");
       System.exit(0);
   }
}
```

Next, create the working class. The method "executeSomething" can of course be anything you want to begin accomplishing your tool's purpose:

```
import java.lang.*;
public class ToolImplementer extends Object {
   public ToolImplementer() {
       super();
       System.out.println("Creating a ToolImplementer instance");
   }
   public void executeSomething() {
       System.out.println("This is a ToolImplementer instance method");
   }
}
```

Finally, create any other Java classes that you need for your tool. And that's all there is to it!

WebObjects 4: Preventing Zombie Processes on Solaris

Q: My WebObjects 4 application is running on a Solaris server; my database is running on a separate system. If the database shuts down, zombie processes are created on the WebObjects server machine. How can I prevent this?
This article has been archived and is no longer updated by Apple.
A: Add this line to the sqlnet.ora file on the Oracle client system:

BEQUEATH_DETACH=yes

The oracle executable will now catch the child signal from the SQLNet connection, preventing the creation of zombie processes. This value is set when the Oracle server is installed, which is why this problem does not occur if the WebObjects application and the Oracle database are installed on the same system.

WebObjects 4: Using Jikes With WebObjects on Windows NT

Jikes is an open source Java compiler developed by IBM for quick, compatible Java code compilation. This article describes how to replace the default Java compiler with Jikes in WebObjects 4 on Windows NT. This is an unsupported procedure to be used at your own risk. Apple Computer provides no support or warranty for this process.

For more information or to obtain Jikes, please visit IBM's Jikes web page at:

http://www10.software.ibm.com/developerworks/opensource/jikes/project/

This article has been archived and is no longer updated by Apple.

The Easy Way

There are two ways to use Jikes with WebObjects and Project Builder. The first and simplest way is to replace the default Java compiler. Simply:

- Rename the existing compiler binary, javac.exe, and move it to a directory not in your system's classpath
- Rename the Jikes compiler to javac.exe, and move it to a directory in your system's classpath

This should allow you to compile using Jikes. However, since the Jikes error stream is different than the stream ProjectBuilder expects from Sun's javac, the build panel will not display errors and link to source files correctly.

The Hard Way

A better way to integrate Jikes into your environment is to integrate Jikes into Project Builder as an alternate compiler. To do this, you'll need to:

- Download the **jikesSpec.plist** and **jikes.bat** files from Apple's FTP servers
- Make sure jikes.exe and jikes.bat are in your system path
- Edit the Executables statement in jikesSpec.plist, replacing "e:/usr/local/bin/jikes.bat" with the path to your jikes.bat file
- Copy the jikesSpec.plist file into $NEXT_ROOT/Developer/Makefiles/Resources/jikesSpec.plist
- Restart ProjectBuilder

Project Builder should now display "IBM Jikes" as an option in the Project Build Attributes inspector's "compiler" popup. With this method, errors will be more likely to be properly highlighted in the build panel. The jikes.bat file simply runs the jikes compiler with the +E flag, which causes error messages to come out on a single line, allowing ProjectBuilder to pick out the filename and line number correctly in most cases. The jikesSpec.plist file is similar to the javaSpec.plist file, with additions for the different warning and error formats. This file only allows the use of Jikes on Windows NT. For more information on customizing Spec.plist files, see the documentation under $NEXT_ROOT/Developer/Makefiles/Resources/compilers.readme

Disclaimer

Whichever way you use to integrate Jikes, remember that Apple has not tested and will not guarantee or provide support for it; follow these instructions at your own risk.

WebObjects 4: Changing the default page in a WebObjects application

This article describes how to change the default page of a WebObjects application from the page defined by Main.wo to the page or WOComponent of your choice.
This article has been archived and is no longer updated by Apple.

Introduction

By default, a WebObjects app opens to a page named "Main". Any reference to "Main" in a hyperlink, action method, or dynamic element directs users to this page named "Main". Sometimes WebObjects developers wish to change this "default" page to a different WOComponent.

You can change this default page by overriding a method in your WOApplication subclass. In Objective C, the method is:

```
- (WOComponent*)pageWithName:(NSString*)aName inContext:(WOContext *)aContext
```

In Java, the method is:

```
public WOComponent pageWithName(java.lang.String pageName, com.apple.yellow.webobjects.WOContext context).
```

The source code examples below demonstrate how to implement the change. Please note that if you override pageWithName:inContext: in this way, all references to "Main" in your application will now be references to "DiffDefPage". Users are no longer able to access the Main.wo component.

Example: Objective C

```
In Objective-C, add the following code to your Application.m file:

- (WOComponent *)pageWithName:(NSString *)pageName inContext:(WOContext *)context
{
// redirect any requests for the Main to DiffDefPage
if (!pageName || [pageName isEqualToString:@"Main"])
{
return [super pageWithName:@"DiffDefPage" inContext:context];
}
return [super pageWithName:pageName inContext:context];
}
```

Example: Java

In Java, add the following code to your Application.java file:

```
public WOComponent pageWithName(String pageName, WOContext context)
{
// redirect any requests for the Main to DiffDefPage
if ((pageName == null) || (pageName.equals("Main")))
{
return super.pageWithName("DiffDefPage", context);
}
return super.pageWithName(pageName, context);
}
```

Macintosh LC and Macintosh LC II: 16-Bit Color

John Sculley said something at MacWorld about the support of "thousands" of colors with 16-bit color on the Macintosh LC. Is that true?

This article has been archived and is no longer updated by Apple.
Yes, it is true. This was announced at the introduction of Macintosh LC.
The product is called the Macintosh LC 512K VRAM SIMM (M0517LL/A) and was made available in February 1991.

The standard Macintosh LC and the new Macintosh LC II support these video configurations:

- Macintosh 12-Inch Monochrome Display: 2, 4, or 16 shades of gray

- Macintosh 12-Inch RGB Display: 2, 4, 16, or 256 colors

- AppleColor High-Resolution RGB Monitor (13-inch): 2, 4, or 16 colors

With the Macintosh LC 512K VRAM SIMM (M0517LL/A) installed, the Macintosh LC and Macintosh LC II support these video configurations:

- Macintosh 12-Inch Monochrome Display: 2, 4, 16, or 256 shades of gray

- Macintosh 12-Inch RGB Display: 2, 4, 16, 256, or 32,000 colors

- AppleColor High-Resolution RGB Monitor (13-inch): 2, 4, 16, or 256 colors

Note

The Macintosh LC and LC II do not support full 16-bit color, which allows over 65,000 colors.

NeXTSTEP 3.3 Patch 3 Overview

This document contains an overview and download information for Apple's Patch 3 for NeXTSTEP Release 3.3 and EOF 1.1. Apple recommends that all users of NeXTSTEP 3.3 install this patch set. Users of NeXTSTEP versions prior to release 3.3 should register for and install an upgrade from Apple to NeXTSTEP 3.3 before installing this patch. For more information, please see the **Software Registration web page**.

NeXTSTEP 3.3 Patch 3 supercedes NeXTSTEP 3.3 Patch 2, released in July of 1999. If you have already installed Patch 1 or 2 on your system, you can install this patch over your existing installation. If you have not installed Patch 1 or 2, you do not need to.

This patch does not address EOF 1.1. EOF 1.1 users should see **document 70084** for an explanation of some manual steps they can take to avoid some Year 2000 issues.

The NeXTSTEP Current Patch List, **document70038**, contains information on all available patches and workarounds for all versions of NeXTSTEP, including EOF patches. Please read this document if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.
NeXTSTEP 3.3 Patch 3 comes in several packages, depending on the user platform version. For Intel and NeXT-branded Motorola hardware platforms, download the file **NS33CISCUserPatch3.tar**. For Solaris and HP-UX platforms, download the file **NS33RISCUserPatch3.tar**.

In addition, there is a NeXTSTEP 3.3 Patch 2 Developer package, **NS33DeveloperPatch2.tar**. This is a multi-architecture installer package, and should be installed on systems that have NeXTSTEP 3.3 Developer installed. IMPORTANT: If you are installing the Developer patch, please **read document 70084** to learn how to manually correct some issues with the developer components of EOF 1.1.

If you use Enterprise Objects Framework on your system, it should be installed before you install NeXTSTEP 3.3 Patch 3. Patch 3 includes fixes in system components that were originally installed by either EOF or the Foundation User Patch. The NeXTSTEP and EOF software packages should be installed in the following order:

- NeXTSTEP 3.3 User
- NeXTSTEP 3.3 Developer (optional)
- EOF 1.1 User (optional)
- EOF 1.1 Developer (optional)
- NeXTSTEP 3.3 Patch 3 User package
- NeXTSTEP 3.3 Patch 2 Developer package (optional)

After download, you may need to decompress the file with the command (example):

```
tar xf NS33CISCUserPatch3.tar
```

This will unpack the single 'tar' file used for download into the .pkg format compound document used by the NeXTSTEP installer. Your web browser or FTP client may perform this step for you.

To install NeXTSTEP 3.3 Patch 3, perform the following steps:

1. Log in as root on your NeXTSTEP system. If you're not sure how to log in as root, see your system administrator.
2. Double-click on the **NS33CISCUserPatch3.pkg** (or **NS33RISCUserPatch3.pkg**) file.
3. Click the Install button in the Installer package window. An Install Package panel will open.
4. Click 'Install' in the Install Package panel and, when prompted for confirmation, click OK to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.
5. If you do not need to install the Developer patch, skip to step 8 to complete the installation. To install NeXTSTEP 3.3 Developer Patch 2, double-click on the **NS33DeveloperPatch2.pkg** file.
6. Click the Install button in the Installer package window. An Install Package panel will open.
7. Click 'Install' in the Install Package panel and, when prompted for confirmation, click OK to proceed. The Installer window displays information about the progress of the installation, which may take several minutes.
8. When the installation completes, the system must be rebooted. Log out and use the reboot button on the login panel.

Issues Addressed

Corrected in NeXTSTEP 3.3 Patch 3

'gnutar' hangs on recursive links.
Apple reference # 2365132

ISSUE:
The version of 'gnutar' shipped with NeXTSTEP 3.3 Patch 2 CISC and RISC is based on GNU tar-1.12 and expects a later version of lstat than that found on NeXTSTEP. Some symbol names changed in the newer version of lstat. If these newer symbol names are not found, 'stat' is used instead of 'lstat' and 'gnutar' hangs on recursive links.

RESOLUTION:
'gnutar' has been modified to work correctly with both older and newer versions of lstat.

'at' schedules jobs incorrectly when no date is specified
Apple reference # 2358294

ISSUE:
The 'at' command in NeXTSTEP 3.3 Patch 2 for CISC and RISC scheduled jobs incorrectly when no date was specified.

RESOLUTION:

The version of 'at included in this patch schedules these jobs correctly.

Missing hard link to /usr/ucb/w
Apple reference # 2351777

ISSUE:
/usr/ucb/uptime, normally a hard link to /usr/ucb/w, was no longer linked after NeXTSTEP 3.3 patch 2 was installed.

RESOLUTION:
This patch restores this missing link.

Missing hard link to /bin/sh
Apple reference # 2351777

ISSUE:
/bin/jsh, normally a hard link to /bin/sh, was no longer linked after NeXTSTEP 3.3 patch 2 was installed.

RESOLUTION:
This patch restores this missing link.

Corrected in NeXTSTEP 3.3 Developer Patch 2

Indexing Kit example used two-digit date field
Apple Reference #2332090, 2331940

ISSUE:
The example application for the Indexing Kit used a two-digit year date entry field, which caused columns to be incorrectly sorted by date.

RESOLUTION:
The example application now uses a four-digit year for data entry and for sorting.

DBKit date formatter example used two-digit year format
Apple Reference #2337035, 2337355

ISSUE:
The date formatter example for DBKit only accepted dates of the form MM/DD/YY.

RESOLUTION:
The example now accepts dates of the form MM/DD/YYYY.

Corrected in NeXTSTEP 3.3 Patch 2

'at' command executed jobs queued after 31 Dec. 1999 before scheduled run date
Apple Reference #2324143, 2325511

ISSUE:

The name of the spool file which the 'at' command created for storing a job encoded the job's run date using a two-digit year date format. This caused 'atrun' to execute jobs queued for dates after 31 Dec. 1999 before they should be run.

RESOLUTION:
'at' now creates spool filenames that use four-digit years.

'atq' command formatted dates incorrectly
Apple Reference #2324153, 2325512

ISSUE:
The 'atq' command used the strings '19%2d' or '19%d' for formatting the last run date for the 'at' queue and the date at which the individual entries should be run.

RESOLUTION:
This command now formats the date with the correct century. To handle legacy filenames, two-digit dates less than '69' and three-digit dates are interpreted as being in the 21st century.

Leap year calculation in 'at' command didn't include 400-year rule
Apple Reference #2324154, 2325513

ISSUE:
The leap year calculation in the 'at' command failed to take into account the 400-year rule, resulting in incorrect behavior after leap day in the year 2000.

RESOLUTION:
This calculation has been corrected.

'atq' leap year calculation didn't include 400-year rule
Apple Reference #2324158, 2325514

ISSUE:
The leap year calculation in the 'atq' command failed to take into account the 400-year rule, resulting in incorrect behavior after leap day in the year 2000.

RESOLUTION:
This calculation is corrected.

'atrun' command assumed two-digit year for spooled jobs
Apple Reference #2324160, 2325515

ISSUE:
The 'atrun' command assumed that spooled jobs were named with a two-digit year format.

RESOLUTION:
'atrun' now handles job filenames with two-, three-, and four-digit years correctly.

RCS did not work correctly after 1999
Apple Reference #2327725, 2328459

ISSUE:
The RCS version shipped with NeXTSTEP 3.3 did not work correctly after 1999.

RESOLUTION:
This patch upgrades to RCS version 5.7, which handles dates past 1999. Refer to the RCS documentation for information on additional changes, features and bug fixes in this version of RCS.

'/bin/date' command didn't allow dates later than 1999 to be set
Apple reference #2328124, 2327723

ISSUE:
The '/bin/date' command didn't allow the system date to be set to any year past 1999. A secondary problem resulting from this error was that users of the Preferences application were unable to set a date later than 1999.

RESOLUTION:
The 'date' command now correctly handles two-, three-, and four-digit years for dates in the valid UNIX range (1 Jan 1970 00:00:00 - 31 Dec 2037 23:59:59). Two-digit years from 70-99 are interpreted as 1970-1999; two-digit years from 00-37 are interpreted as 2000-2037. Three-

digit years from 070-099 are interpreted as 1970-1999; three-digit years from 100-137 are interpreted as 2000-2037.

'gnutar' command didn't accept dates later than 1999
Apple Reference #2328449, 2327724

ISSUE:
The 'gnutar' command has an option to only write files newer than a given date, but version 1.11.2, the version shipped with NeXTSTEP 3.3, didn't accept dates past the end of 1999, even using four-digit years.

RESOLUTION:
'gnutar' has been updated to version 1.12, which accepts dates after 1999.

'zsh' command could have displayed incorrect date in command prompt after 1999
Apple Reference #2331360, 2332042

ISSUE:
The 'zsh' command could be configured to display the date in the command prompt. This date display did not function correctly after 1999.

RESOLUTION:
This problem is corrected.

NSCalendarDate's two-digit year format returned three-digit years after 1999
Apple Reference #2331365, 2331975

ISSUE:
NSCalendarDate's +descriptionWithCalendarFormat: method's two-digit year format (%y) returned three-digit years after 1999. For example, '2000' was displayed as '100,' rather than '00'.

RESOLUTION:
This method now returns an appropriate two-digit year when the %y format is employed. Users are strongly cautioned that two-digit year values are inherently ambiguous and can result in serious software errors.

'enscript' command displays incorrect year in file timestamp after 1999
Apple Reference #2331367, 2331658

ISSUE:
The 'enscript' command has an option that printed a file's timestamp as a page header. This header displayed an incorrect year after 1999.

RESOLUTION:
This problem is corrected.

'nroff' and 'troff' macros displayed two-digit dates that were incorrect after 1999
Apple Reference #2331436, 2331978

ISSUE:
The macros used by 'nroff' and 'troff' automatically generated certain date values which displayed two-digit years, and which were incorrect after 1999.

RESOLUTION:
These macros now display correct four-digit years both before and after 2000 for automatically generated dates.

NSCalendarDate calendar format methods interpreted all two-digit dates as 20th century
Apple Reference #2331983, 2332180

ISSUE:
NSCalendarDate's -dateWithString:calendarFormat: and -initWithString: calendarFormat: methods interpreted all two-digit dates as being in the 20th century; i.e., "00" was interpreted as "1900".

RESOLUTION:
These methods now follow the Microsoft Exceltm convention used in later versions of Foundation, where two-digit dates less than 30 are interpreted as 21st century dates (2000-2029) and two-digit dates 30 and greater are interpreted as 20th century dates (1930-1999). Users are strongly cautioned that two-digit year values are inherently ambiguous and can result in serious software errors.

Motorola DSP assembler output incorrect page header in 2000
Apple Reference #2331999, 2332113

ISSUE:
The Motorola 56K DSP assembler output an incorrect page header in year 2000.

RESOLUTION:
This problem is corrected.

Motorola DSP librarian output incorrect library file dates after 1999
Apple Reference #2332012, 2332136

ISSUE:
The Motorola 56K DSP librarian output incorrect dates in library file listings after 1999.

RESOLUTION:
This problem is corrected.

Motorola 56K DSP Linker output incorrect page header
Apple Reference #2333271, 2333840

ISSUE:
The Motorola 56K DSP Linker output an incorrect page header in year 2000.

RESOLUTION:
This problem is corrected.

'/usr/ucb/w' displayed year values later than 1999 incorrectly as three-digit values
Apple Reference #2334633, 2333834

ISSUE:
The '/usr/ucb/w' command displayed the year value in date stamps after 1999 as three digits, i.e., the year 2000 displayed as '100' rather than '00'. Although the use of a two-digit year format is not preferred practice, changing the date format to use four-digit years could cause errors in programs that call the 'w' command.

RESOLUTION:
'/usr/ucb/w' now outputs two-digit years after 1999. It is the responsibility of the calling program to resolve the ambiguity of the two-digit year values in w's output.

Generated date for text pasted into new mail message incorrect for dates after 1999
Apple Reference #2334672, 2333902

ISSUE:
When creating a new message in a mailbox by pasting text into the mailbox, the generated date for the message was not correct for dates after 1999.

RESOLUTION:
This problem is corrected.

FTP daemon sent wrong file modification time for files created or modified after 1999
Apple Reference #2336094, 2336098

ISSUE:
The FTP daemon's 'MDTM' command sent the wrong modification time in reply to files created/modified past 1999. For example, the year 2000 was formatted as 19100.

RESOLUTION:
A correcting factor allows the 'MDTM' command to correctly format dates after 1999.

Fax software date stamps used two-digit year format
Apple Reference #2337034, 2337450

ISSUE:
The date stamps written by the fax software used a two-digit year format, and the aging code which detected and removed old fax log files failed when the year changed from '99' to '00'.

RESOLUTION:
To avoid causing problems with any software that might parse the fax log date stamps, the two-digit year format is still used, but the aging algorithm is modified to behave correctly both before and after the year 2000.

Verbose file listing from the 'tp' command printed incorrect two-digit dates after 1999
Apple Reference #2337845, 2338047

ISSUE:
The verbose file listing from the 'tp' command printed two-digit dates that were incorrect after 1999.

RESOLUTION:
The 'tp' command is now modified to output a correct four-digit date both before and after 1999.

Active.mbox had two-digit year in the Date header
Apple Reference #2339224, 2338436

ISSUE:
The welcome email message from Steve Jobs had a two-digit year in the header.

RESOLUTION:
This message now displays a four-digit year.

'Mail.app' read receipt date parsing could have failed for two-digit years less than 70
Apple Reference #2339301, 2338432

ISSUE:
The 'Mail.app' date parsing for read receipts could have failed for two-digit years less than 70.

RESOLUTION:
The 'Mail.app' date parsing is now modified to accept two-digit years less than 70 and treat them as within the 21st century. Two-digit years from 70-99 are interpreted as within the 20th century. This problem is very similar to Apple reference 2344011/2338435, also corrected in this patch. Additionally, three-digit years are interpreted as an offset from the year 1900, so year '100' is taken to be 2000.

Invalid date arguments could crash Sybase 4.6
Apple Reference #2340499, 2339379

ISSUE:
In the Sybase 4.6 version that shipped with NeXTSTEP 3.3, lack of error-checking code could cause an array underflow when certain invalid date values are passed. This error causes Sybase's Year 2000 compliance test suite to crash.

RESOLUTION:
More complete error checking now detects the problem date values and raises an appropriate Sybase exception.

'Mail.app' read receipt date parsing could have failed for two-digit years less than 70
Apple reference #2344011, 2338435

ISSUE:
The 'Mail.app' date parsing for read receipts could fail for two-digit years less than 70.

RESOLUTION:
'Mail.app' has been modified to accept two digit years less than 70 and treat them as 21st century years. Two-digit years from 70-99 are interpreted as 20th century. Additionally, three-digit years are interpreted as an offset from the year 1900, so year '100' is taken to be 2000. Note, however, that the date value being parsed is in the form of a literal string taken from the received mail's header (which is displayed with the message) and there is no way to modify this string to display the year as a four-digit value. If mail is received with a date in year '100', the value '100' is displayed as the year, but internally the year is evaluated as 2000.

'sendmail' date header used two-digit year format
Apple reference #2345707, 2345799

ISSUE:
The 'Date:' header line of mail messages created with the '/usr/ucb/mail' command showed the date and time of creation using a two-digit year format.

RESOLUTION:
The 'mail' command now writes a four-digit year in the 'Date:' header.

'/usr/bin/refer' command assumed all references had dates in 20th century
Apple reference #2345894, 2345940

ISSUE:
The 'nroff' and 'troff' preprocessor, '/usr/bin/refer,' discarded references with dates whose century was not '19' in certain circumstances.

RESOLUTION:
The 'refer' command now recognizes bibliographic references in any century.

'at' command sometimes scheduled jobs incorrectly after Feb 29 in leap years
Apple reference 2346578, 2346551

ISSUE:
The calculation in the 'at' command used to determine the day of the year that a job should execute didn't properly account for the additional day in leap years when the user entered the job in the year prior to a leap year. For example, if a user scheduled a job for March 2, 2000 in June of 1999, with the syntax 'at 8am Mar 2,' the 'at' command incorrectly scheduled the job for March 1, 2000.

RESOLUTION:
The day-of-year calculation used by 'at' for scheduling jobs in the next year is corrected to account properly for leap years

Year wasn't set correctly after 1999 in i386 and m68k real-time clock chips
Apple reference #2253936

ISSUE:
The year value wasn't stored correctly after 1999 in the RTC chip on i386 and m68k hardware. One symptom of this error was that users of the Preferences application were unable to set a date later than 1999. This issue only affected the CISC version of NeXTSTEP 3.3.

RESOLUTION:
This problem has been corrected.

NeXT-based 68HC68T1 clock chip doesn't store the century
Apple Reference #2339331

ISSUE:
The 68HC68T1 clock chip in NeXT computers didn't store the century of the year. This issue only affected the CISC version of NeXTSTEP 3.3.

RESOLUTION:
Since the clock chip uses the "every fourth year is a leap year" calculation, this won't cause any problems until 2100.

Hewlett-Packard real-time clock used a two-digit year
Apple Reference #2333833

ISSUE:
The Hewlett Packard real time clock used a two-digit year, and the code that set the real time clock date behaved improperly after 2000. This issue only affected the RISC version of NeXTSTEP 3.3.

RESOLUTION:
Two-digit years less than 70 are now interpreted as 21st century, while years greater than or equal to 70 are interpreted as 20th century.

Corrected in NeXTSTEP 3.3 Patch 1

HCRX & HCRX24 cards are not supported
Apple Reference #45838, 54418, 54461, 54462
The new Hyperdrive graphics cards (HCRX and HCRX24) are now supported. Note that although the HCRX card is only 8 bits deep, it can be run in "color-recovery" mode as a 24-bit device. If you are running the HCRX card as the console boot device in 8-bit color mode, turn off boot graphics in your configuration to obtain the proper color map.

MIDI driver doesn't load
Apple Reference #50481

This has been fixed.

HP getty panic
Apple Reference #52993
When an HP computer running NEXTSTEP Release 3.3 boots with the serial driver configured, a getty turned on for a serial port, and the modem connected and turned on, the system panics. This has been fixed.

HPPA 8-bit color problems
Apple Reference #54419
On HPPA machines, choosing 8-bit color leads to color glitches. 8-bit color modes had issues with bad color map entries. This has been fixed. Note, however, that a related bug (#54420) has not been fixed. This bug arises when you change the brightness on multi-headed HP 715'sPit causes color map glitches on 8-bit displays. The issue seems to occur only after power cycling and booting with boot graphics. Booting verbosely should avoid the issue.

gdb and floats
Apple Reference #24436
gdb does not interpret floating point numbers correctly when specified as message arguments. This has been fixed.

Miscellaneous gdb panics
Apple Reference #50727, 54401
gdb occasionally hangs or panics when used with certain applications. This has been fixed.

gdb's *step: command behaves like *next
Apple Reference #52634
*step: now steps into methods, instead of stepping over them.

Stack frames in gdb's browser are reversed.
Apple Reference #54968
Between NEXTSTEP Release 3.2 and Release 3.3 the top-to-bottom order in which stack frames are listed in the Edit/Browser tool were inadvertently reversed, so that the outermost function appeared at the bottom instead of the top. This was not done in an internally consistent way, so that if you clicked on the third stack frame from the bottom, for instance, Edit took you to the third one from the top. This has been fixed so that it works the way it did in NEXTSTEP 3.2.

Cached kmsgs not properly initialized
Apple Reference #51192
When using a cached kmsg, the ikm_delta field was not being initialized. This is especially important in the exception handing code when sending the exception message. Cached kmsgs are now properly initialized.

ipc hash leak
Apple Reference #54071
Certain procedures can cause the kernel to hang due to an ipc hash leak. This has been fixed.

Incorrect results from exp()
Apple Reference #54173, 54399
libc's exp() gives incorrect results on Intel-based computers. This has been fixed.

Memory leak in _openDefaults
Apple Reference #54226
_openDefaults can leak 1024 bytes per invocation. This has been fixed.

Control words and longjmp
Apple Reference #54674
longjmp did not preserve the FPU control word across fninit. This has been fixed.

Packet size negotiation logic is flawed
Apple Reference #54180
NetWare performs packet size negotiation during the server discovery process. This negotiation process is flawed. For example, suppose that the client station first sent its favorite packet size (1024 bytes for Ethernet, for example) to the server on the other side of a LAN switch. The server would then send back its favorite packet size (say, 4096 for FDDI) which the client simply accepted as the negotiated block sizePdespite the fact that this size is illegal for Ethernet. This issue arose because neither the server nor the client are aware of the existence of the LAN switch that is bridging the FDDI and Ethernet LANs. The patch causes the workstation to ignore negotiated packet sizes larger than what its immediate medium can support. This should be sufficient until such time as NeXT implements "burst mode" transfers.

Network socket `bind' fails to detect *address in use
Apple Reference #54216
A bug was introduced during the porting of Stanford's IP Multicast code that allowed multiple local clients to bind to the same IP address (that is, the code failed to detect that the address was in use). This patch corrects that error.

Various netinfo bugs

Apple Reference #36740, 39778, 49580, 49585, 49607, 49899, 50175, 51088, 51809, 51944, 53423
A number of bugs were fixed in netinfo. The following are some of the more notable bugs that were fixed:

- 39778: If you have a second account with a uid of 0, netinfo authentication can fail. If a netinfo domain had multiple users with the same UID, authentication for that UID would be unreliable.
- 49607: lookupd should number domains starting at 1. Minor change. When lookupd received a SIGUSR2 to log it's current connections, it numbered domains started at 0 rather than 1.
- 49899: Permission denied even when _writers is *. Directories with _writers * were only writable by root.
- 50175: nidomain must byte-swap master's address. This bug caused nidomain -c to fail to create clones on Intel-based computers. The master's IP address was byte-swapped, resulting in an incorrect and unusable database.
- 51088: Memory smasher in netinfod. This bug would cause random netinfo crashes. It was the result of ni_writeprop() freeing some memory twice.
- 51809: netinfod[PID]: tag test: can't get masters /machines/ip_address/I^AT*s^ directory. The netinfo clone start-up configuration checking routine had a couple of syslog messages that were missing an argument. If a clone was mis-configured, it would print a garbled error message.
- 51944: file name is freed, then used. A very rare bug that only occurred if a file system error occurred while the server was shutting down, and it got an error while writing the checksum file.
- 53423 netinfod shouldn't call ni_error() - localization calls getpwuid(). A rare bug that could cause netinfo to hang before printing an error message if it detected an internal error.

NetInfoManager won't create clones on Intel-based computers
Apple Reference #54242
This bug prevented NetInfoManager from creating clone netinfo servers on Intel-based computers. The bug affected clone creation using both the *Servers: panel and the *Manage Hierarchy: panel. Clones created using NetInfoManager would have the master's Internet address reversed, and as a result database initialization and updates would fail. This has been fixed.

SimpleNetworkStarter messes up mail server configurations
Apple Reference #54245
This bug caused SimpleNetworkStarter to install its mail-server package every time it ran. The result was that the last computer that was configured using SimpleNetworkStarter would really be the mail server. Confusing information would be left behind on other computers, and mail would not be correctly configured. This has been fixed.

netinfo's clone self-check has RPC issues
Apple Reference #54920
This bug caused sporadic start-up issues on clone netinfo servers. The bug was caused by errors in the clone configuration self-check routines that ran at start-up time. These self checks have been disabled in this update.

localized Colors... menu item in Terminal
Apple Reference #49523
There was no Colors.. menu item in localized versions of Terminal. This has been fixed: the Colors command is now present in the localized versions of Terminal.

Various cosmetic fixes for localized text
Apple Reference #49525, 49559, 50876, 51668, 52463
Various cosmetic fixes were made to text localization:

- Raising the color panel from any application while you are working in a language other than English produces a *parse error: message in the console window (and the panel contains English text).
- The window title that is displayed while loading Preferences is in English, even when you are working in a language other than English.
- When working in French, Configure's Inspector.nib shows some English text.
- When working in French, some configuration text fields aren't wide enough to contain entire sentences.
- The Spanish version of Loginwindow's preferences panel was poorly formatted.
- Several of the localized Preferences, Configure, and SimpleNetworkStarter files were fixed to provide cleaner UI.

UserManager localization bugs
Apple Reference #50792, 50794, 51190, 54229, 54279
UserManager had a number of bugs in the various localized versions:

- The User Info confirmation panel does not display the path of the login shell when you are working in French.
- The Program Hooks pop-up menu has no valid labels in the Group Default Configuration panel when you are working in French.
- Some fields in the Create Bulk panel aren't properly localized.

- Clicking on the User Account login name format pop-up list after creating multiple users in a domain and then reading an input file containing user names causes UserManager to crash.
- This issue still exists when running UserManager in Swedish on Intel or NeXT architectures. As a workaround, run UserManager in another language.
- The Group menu doesn't work when working in German.

This patch release also fixes some connections in the nib files for the localized versions of UserManager so that now creating bulk accounts, creating groups, and inspecting group defaults all work properly in the localized versions.

Cannot choose a language other than English when you create a new user account
Apple Reference #51223
New template files were added so that system administrators will be able to create new user accounts with certain localization defaults already set. If you are a system administrator and would like to use User Manager to create new user accounts with defaults localized for French, German, Italian, Spanish, or Swedish, you need to select all of the languages when you install the patch. This will ensure that all of the default files are available for your use in usr/template/languages. Note that this will also install other updated language files that are included on the patch. If you use Preferences to select another language that has not been previously installed from the original release software, these updated files would appear in that language while the rest of the UI files in a particular application would appear in the next language you have selected in Preferences which has been installed.

A related bug still exists, however: if you install NEXTSTEP Release 3.3 using one of the European languages and then create an English user account with UserManager, when the new user logs in Workspace will use the language that you chose during installation, instead of English. The user can work around the issue by simply choosing the proper language in Preferences and then logging out and logging back in again. Note that new user accounts are only affected in this way if English is chosen when creating the user account.

Shift-hyphen does not produce an underscore in UK keyboard mapping
Apple Reference #54171
The *alt: and *shift: keys were reversed in the UK keyboard mapping file. This has been fixed.

Fixed Pitch Font issues in non-English languages
Apple Reference #54228
Selecting Fixed Pitch Font in Font Preferences while working in a language other than English caused Preferences to crash. This has been fixed.

VM allocation in WindowServer
Apple Reference #54132
The WindowServer should use vm_allocate instead of malloc for backing storePcurrently, it almost never gives VM back to the operating system. This has been fixed.

Crash while displaying images
Apple Reference #54134, 54138
Certain images, displayed in certain graphics modes, can crash the WindowServer. This has been fixed.

12-bit window flushing delays
Apple Reference #54137
Flushing 12-bit windows on 24-bit displays takes longer than it should. This has been fixed.

cu and tip incorrectly set the UID
Apple Reference #51555, 51785
cu and tip incorrectly set the UID. This has been fixed.

SoftPC filename length
Apple Reference #51590
Use of DOS filenames greater than 31 characters in length causes issues in SoftPC. This has been fixed.

pbs and appkitServer launched with incorrect group permissions
Apple Reference #52531
pbs and appkitServer now launch with the correct group permissions.

CERT Advisory: sendmail vulnerabilities.
Apple Reference #52842, 56026
The sendmail security vulnerabilities described in CERT Advisory CA-95:05 have been fixed. Contact CERT for more details.

Services don't register in ProjectBuilder
Apple Reference #54217
None of the Services items were active in the version of ProjectBuilder supplied with NEXTSTEP Release 3.3. For instance, third-party source code control apps such as DevMan didn't function as advertised. This has been fixed.

Floppy operations don't work as intended
Apple Reference #54220
The floppy operations in workspace were broken. For instance, a floppy was not represented by the proper DOS, MAC, or NeXT floppy icon; instead, a folder icon was displayed. Or, after mounting a floppy (with Check for Disks), the disk was mounted but the Disk menu contained Check for Disks and Eject onlyPit was missing Initialize. These bugs have been fixed.

Internal error in rld
Apple Reference #54260
rld would sometimes get the internal error: *lookup_symbol() failed. This has been fixed.

Multiple devices in Add panel
Apple Reference #54428
Configure treats the last byte of the EISA id as a *don't care: byte. This fixes a issue where Configure would show multiple instances of some devices in the *Add Devices: panel.

Failure to read multiple backups on HPPA machines
Apple Reference #55452
Reading of multiple files/backups failed. Creation of multiple backups on the same tape was not a Issue, but only the first backup could be read on a HP platform.

OPENSTEP Year 2000 Technical Tips

This article discusses ways developers can avoid causing Year 2000 problems in their code, including some issues relating specifically to Apple's OPENSTEP and WebObjects frameworks and API's. This article does **not** discuss the Year 2000 compliance status of any Apple product; for Y2K compliance information, see the Apple Year 2000 main page at http://www.apple.com/about/year2000 .

The following are tips for programmers; we hope they will help you avoid some common problems in your code, and identify problems in your legacy code for remediation.
This article has been archived and is no longer updated by Apple.

Working with Dates in WebObjects

A detailed overview of date handling in WebObjects is now available for **download in PDF format**.

Use Consistent Date Handling

Consistency in date hanlding makes maintaining and fixing date-handling code easier. Apple recommends that you always use the Foundation date and time API's when you need to write date-handling code for OPENSTEP or WebObjects.

Don't Divide By an NSTimeInterval Value

Dates are represented in the Foundation framework with **NSDate** and **NSCalendarDate** objects and **NSTimeInterval** values. An **NSTimeInterval** object is essentially a C-language double (**NSTimeInterval** can represent intervals of approximately 10,000 years with sub-millisecond accuracy). **NSDate** and **NSCalendarDate** store the date that they represent with an **NSTimeInterval** which represents the time delta in seconds from the Foundation reference date (00:00:00 Greenwich Mean Time January 1, 2000). Since the internal time representation will transition across zero at the reference date, there will be a brief instant (on the order of microseconds in length) during which an **NSDate** object created to represent the current time will have an **NSTimeInterval** of zero. An **NSTimeInterval** of zero has no special significance to **NSDate** or **NSCalendarDate**, but applications that use the **NSTimeInterval** of a date object in division should protect against division by zero. This is unlikely to occur in real-world applications.

Avoid Two-Digit Date Formats

Always use four-digit years when formatting dates for input or output; a four-digit year is the **only** unambiguous way to refer to any date. The Foundation framework's date formatting objects may interpret two-digit year values in unexpected ways, and using the two-digit "%y" format allows no way for a user to present a date unambiguously and may cause additional problems; for example, typing "2004" into a two-digit year formatted field result in a value of "20" being used and "04" being truncated. Instead, use the four-digit "%Y" year format.

OPENSTEP: OPENSTEP and Windows 2000

Q: When Windows 2000 is released, will OPENSTEP 4.2 (or an earlier version of OPENSTEP) run on it?
This article has been archived and is no longer updated by Apple.
A: OPENSTEP Enterprise was developed and tested using Windows NT 4.0. It was not developed for, nor tested on, Windows 2000. Apple does not warrant that any Apple/NeXT products released for Windows NT 4.0 (or earlier), such as OPENSTEP 4.2, will work on Windows 2000. Apple does not intend to do comprehensive regression testing of these products on Windows 2000, and does not intend to provide updates and/or patches to make such products compatible with Windows 2000.

OPENSTEP 4.2: Quantrix Problems on Patched OPENSTEP Systems

Q: I've installed OPENSTEP 4.2 Patch 4 or later on my system, and Quantrix will no longer run. How can I continue to use Quantrix under patched versions of OPENSTEP?
This article has been archived and is no longer updated by Apple.
A: Quantrix, a product of Lighthouse Design, Ltd., expects certain specific behavior from the 'gnutar' command. Because of Year 2000 issues with 'gnutar,' OPENSTEP 4.2 Patch 4 and later and NeXTSTEP 3.3 Patch 2 and later replace the version of 'gnutar' that shipped with the operating system with a Year 2000-compliant version. Quantrix cannot use this version of gnutar. As a result, Quantrix cannot create new models. If your preferences are set to create a new model at launch time, Quantrix will hang when starting up.

Users can work around this problem by editing one of the Quantrix configuration files. Using an 8-bit capable text editor such as Edit.app or emacs, edit the file:

```
Quantrix.app/English.lproj/Localizable.strings
```

You should see an entry in this file which looks like:

```
/* path to gnutar executable - DO NOT CHANGE */
"/usr/bin/gnutar";
```

Change this line to read:

```
"/usr/bin/gnutar" = "/bin/false";
```

Quantrix will now run without using any version of 'gnutar'. Apple has not tested and does not provide any warranty for this procedure. Be sure that you use an editor that understands and preserves 8-bit characters; if you use a 7-bit text editor such as vi, Quantrix will not understand the new file.

NeXTSTEP 3.3: Quantrix Does Not Run On Patched NeXTSTEP Systems

WebObjects 4: Preventing Line Breaks In WOSendMail

This article describes why linebreaks appear in electronic mail generated by the WOMailDelivery class and sent by WOSendMail, and how to reduce the occurrence of line breaks that can hurt the overall appearance of your plain text e-mails.
This article has been archived and is no longer updated by Apple.
WebObjects 4 provides a class for generating and sending e-mail called WOMailDelivery. Behind the scenes WOMailDelivery invokes a tool called WOSendMail. To generate a plain text e-mail, you can add the WOExtensions framework to your project and add code like the following...

```
String theMailString =WOMailDelivery.sharedInstance().composePlainTextEmail(from, to, cc, subject, message, false);
```

where message represents the body of the e-mail. The message might be pre-defined, or it might be something a user enters into a WOTextfield on one of the pages of your WebObjects application. See the WOMailDelivery class description for information about the remaining parameters.

Your app would send the message with the following code:

```
WOMailDelivery.sharedInstance().sendMail( theMailString );
```

The resulting e-mail might wrap the lines of text at a seemingly arbitrary pre-chosen length. This can result in ugly line-wrapping for some e-mail clients. Some customers would prefer to eliminate this pre-chosen line length, so that their e-mail clients will wrap the lines based on window size.

According to the SMTP specification, the limit for line length should be 998 characters (leaving 2 characters for carriage return and linefeed). (See http://freesoft.org/CIE/RFC/821/24.htm for more information). WOSendMail defaults to a line length of 76 characters. To change this default, simply add an entry to WOSendMail's defaults database. WOSendMail includes a "LineLength" user default. When the LineLength default is set to a positive integral value, the line wrapping occurs as directed by the user default. Type the following at a shell prompt:

```
defaults write WOSendMail LineLength 998
```

If you have problems, make sure the 'defaults' command is on your path. The executable should be located in $NEXT_ROOT/Library/Executables.

Note: Setting this user default will not prevent line-breaks for e-mails whose line lengths exceed 998 characters. E-mail messages with non-standard line lengths will display differently on different e-mail clients.

OPENSTEP: gnutar changes in Apple patches

Several Apple Enterprise and NeXT products included the GNU 1.11.2 version of tar, which for certain operations did not handle dates after 1999 properly. A newer version of tar based on the GNU tar-1.12 source has been provided in Apple patches for many affected products on Mach, Solaris, and HP-UX platforms. This newer version of tar, while correcting all known Year 2000 issues, may have unwanted side effects for some users. In an effort to minimize these side effects, Apple made some modifications to the standard version of GNU tar-1.12.

This document describes the changes Apple made to the GNU tar-1.12 source. In addition, it discusses potential problems Apple users may encounter using GNU tar-1.12 on older systems, and provides workarounds for them.

This article has been archived and is no longer updated by Apple.

Which products and patches are affected?

The Apple Enterprise Software product patches which include an updated version of gnutar include:

- NeXTSTEP 3.3 Patch 2 and subsequent NeXTSTEP 3.3 patches
- OPENSTEP 4.2 Patch 4 and subsequent OPENSTEP 4.2 patches
- WebObjects 3.1 Patch 1 and subsequent WebObjects 3.1 patches
- WebObjects 3.5.1 Patch 4 and subsequent WebObjects 3.5.1 patches
- WebObjects 4.0.1 Patch 1 and subsequent WebObjects 4.0.1 patches

For complete information on the current patches available for Apple Enterprise Software products, please see the NeXTSTEP Current Patch List, the OPENSTEP Current Patch List, and the WebObjects Current Patch List

Apple modifications to tar

GNU tar-1.12 expects a more recent version of the system header file 'stat.h' than the one shipped with OPENSTEP and NeXTSTEP. Some of the symbols defined in stat.h have changed, including the symbolic link symbol, formerly _S_IFLNK, now S_ISLNK. A test in the file tar-1.12/src/system.h in the GNU source distribution (lines 144-148) defines 'lstat' to be 'stat' if the newer symbolic link symbol is not found, with the result that symbolic links are not processed properly:

```
#include <sys/stat.h>

#ifndef S_ISLNK
# define lstat stat
#endif
```

Since there is code later in the same file which correctly handles the older symbols, Apple modified the code above as follows:

```
#include <sys/stat.h>

#ifndef S_ISLNK
/* # define lstat stat */
#endif
```

This was the only modification made to the GNU tar 1.12 source files for Apple's patches.

Problems which may be encountered due to changes between GNU tar-1.11.2 and GNU tar-1.12

When processing input being read from a pipe, the older version of tar read only the contents of the .tar file and then exited. But tar-1.12 continues to read from the pipe (discarding the data) until the pipe is closed, even after the .tar file ends.

Because of this change, some third-party OPENSTEP and NeXTSTEP applications may not be fully compatible with the gnutar. This is known to affect Quantrix.app and Concurrence.app. Information on a Quantrix-specific workaround is available as **TIL article 70128**.

For other applications, you may need to copy the original gnutar from your installation media and reinstall it on your system. You may need to edit the application binary or an application-specific configuration file to force the application to use this version of gnutar.

Building GNU tar-1.12 on NeXTSTEP or OPENSTEP

In order to build GNU tar-1.12 on NeXTSTEP or OPENSTEP, you must modify one of the files which is automatically generated by the 'configure' script included in the GNU tar-1.12 distribution. To make the modification:

1. Run 'configure'

2. Using a text editor, make the following change in the config.h file:

Change:

/*#undef HAVE_UNION_WAIT */

To:

#define HAVE_UNION_WAIT 1

3. Run 'make' to compile the package.

Consult the INSTALL documentation included in the GNU tar-1.12 distribution for additional information on building the package.

A/UX newfs and Sony Optical Disk Drive

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I have a private Sony SMO-C501-OO (Magneto-Optical disk). I did a newfs and mounted it under A/UX. I've formatted it under SilverLining 5.25 with a Slice 3 partition (287MB) under Macintosh OS. But when I created the newfs on it under A/UX, the options were quite confusing. After several unsuccessful attempts, I chose to recognize it as a 160SC disk, and then the miracle occurs! The newfs command was working perfectly! So my question is:

Is this normal? Does the newfs command recognize the hardware specification of the disk and bypass the /etc/disktab or newfs options, whatever your choice is?

This article has been archived and is no longer updated by Apple.
The problem that you were getting with a smaller size of file system or something confusing about the newfs options was possibly due to the wrong type of disk drive you've chosen when creating the file system via "newfs". We don't know what option(s) of "newfs" syntax you specified. We are not sure if you have the right size of file system (with 287MB) after you chose 160SC disk type.

You should choose a drive type which is closer to your drive specification, or you could create a new entry with the drive physical characteristics (number of sectors/track, number of tracks/cylinder, and the number of cylinders/disk) in /etc/disktab for the particular disk drive. "newfs" reads the information from /dev/disktab for a particular drive type and invokes the /etc/fs/ufs/mkfs program to make a file system for a partition.

WebObjects 3.5.1: Additional gdb Troubleshooting

This article discusses a workaround for a known problem with gdb under WebObjects 3.5.1 on Windows NT.
This article has been archived and is no longer updated by Apple.
The WebObjects 3.5.1 release notes describe the following problem which may occur on Windows NT installations of WebObjects 3.5.1:

gdb breaks on unknown signal

Apple Reference #: 78366

Issue:

gdb breaks at the end of every request-response loop cycle, claiming that it has caught an unknown signal in closesocket.

Workaround:

Use the continue command to continue execution when gdb breaks. To prevent this from happening in the first place, do one of the following :

- *Before running your application in gdb, enter the command set signal-exception 4.*
- *Create a gdb.ini file containing the set signal-exception command and save it in each of your .woa projects. You also can put it in your home directory to affect all projects that you work on.*

In some cases, the solution described may not fully resolve the problem. In these cases, try the following additional step:

Under the Windows NT registry path:

HKEY_LOCAL_MACHINE\\SOFTWARE\\ORACLE

rename the key

OTRACE73

to (for example)

OTRACE73.RENAMED

This is an unsupported procedure and may create unknown side effects with the Oracle database. If problems occur, rename the key to its original name.

WebObjects 4.5: Java FAQ

This article contains frequently asked questions (FAQ) regarding Java in WebObjects 4.5, with answers to those questions.
This article has been archived and is no longer updated by Apple.

Questions answered in this article:

1. What JDK version is used in WebObjects 4.5?
2. Does Apple support Just-in-Time (JIT) compilation with WebObjects 4.5?

Question 1: What JDK version is used in WebObjects 4.5?

Answer: WebObjects 4.5 uses Sun's 1.1.8 JDK on Windows NT and Solaris, and Sun's 1.1.7 JDK on HP-UX. This is the only version officially supported by Apple. In addition, WebObjects 4.5 supports Sun's Swing interface library, version 1.1.1.

Question 2: Does Apple support Just-in-Time (JIT) compilation with WebObjects 4.5?

Answer: JIT functionality is not available in this release of WebObjects. WebObjects applications spend much of their time running compiled framework code; the speed benefits of this approach are greater than would be seen with JIT-compiled Java code.

WebObjects 4.5: Password Protecting the WOStats Page

The WOStats page gives a WebObjects application administrator useful information about their application and its real-world usage. This document explains how to use password protection to keep external requests from accessing your site's statistics page.
This article has been archived and is no longer updated by Apple.

Overview

If WebObjects 4.5 Update 2 or WebObjects Update 3 is installed, the WOStatsPage is protected by default. This document is only relevant if one of the WebObjects updates is not installed.

Related Articles:

By default, the password protection functions of WOStats are disabled. To enable them, you will need to change some of the files in the WOStatsPage project. The exact steps will depend on your operating system. After the function is enabled, it is easy to set a password in your application.

Enabling Password Protection on MacOS X Server

To enable password protection on MacOS X Server, first open the file

```
System/Library/Frameworks/WOExtensions.framwork/Resources/WOStatsPage.wo
```

in the WOBuilder application. If you do not have the development tools installed on this system, you will have to edit the files by hand; follow the instructions for Solaris and HP-UX systems, below.

- After the file is open, switch to the "Text Mode" view. This will display the HTML file in the upper window, and the application .wod file in the lower window.
- In the upper (HTML) window, line 10 is an HTML comment opening code, "<!--". Remove this line and the matching end comment line after the password object.
- In the lower window, find the ALLOWED: WOConditional statement. The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

- In the same window, find the "REFUSED: WOConditional" statement. The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

Password protection is now enabled. Follow the instructions below to set a password for your application.

Enabling Password Protection on Solaris or HP-UX

To enable password protection on a Solaris or HP-UX system, first open this directory under your Apple root directory (usually /Apple or /opt/Apple):

```
Library/Frameworks/WOExtensions.framwork/Resources/WOStatsPage.wo
```

This directory will contains two files, WOStatsPage.html and WOStatsPage.wod. Using a text editor, make the following three changes:

- Line 10 of the WOStatsPage.html file is an HTML comment opening code, "<!--". Remove this line and the matching end comment line after the password object.
- In the WOStatsPage.wod file, find the "ALLOWED: WOConditional" The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

- Also in the WOStatsPage.wod file, find the "REFUSED: WOConditional" statement. The next line will read:

```
condition=YES;
```

Replace this statement with:

```
condition=session.allowedToViewStatistics;
```

Password protection is now enabled. Follow the instructions below to set a password for your application.

Enabling Password Protection on Windows NT 4.0

To enable password protection on Windows NT, first open this directory under your Apple root directory (usually C:\\Apple):

```
Library/Frameworks/WOExtensions.framwork/Resources/WOStatsPage.wo/
```

This directory will contains two files, WOStatsPage.html and WOStatsPage.wod. Using a text editor or WOBuilder, make the following three changes:

- Line 10 of the WOStatsPage.html file is an HTML comment opening code, "<!--". Remove this line and the matching end comment line after the password object.
- In the WOStatsPage.wod file, find the "ALLOWED: WOConditional" statement. Uncomment the next line and comment out the line that reads:

```
condition=YES;
```

The statement should now read:

```
ALLOWED: WOConditional {
condition=session.allowedToViewStatistics;
//condition=YES;
}
```

- Also in the WOStatsPage.wod file, find the "REFUSED: WOConditional" statement. Uncomment the next line and comment out the line that reads:

```
condition=YES;
```

The statement should now read:

```
REFUSED: WOConditional {
condition=session.allowedToViewStatistics;
//condition=YES;
nagate="1";
}
```

Password protection is now enabled. Follow the instructions below to set a password for your application.

Using Password Protection

Once password protection is enabled, set the password in your Application.wos file's **init** method. The syntax is:

```
[[self statisticsStore] setPassword: @"MyPassword"];
```

WebObjects 4.5: Solaris "Can‘t find Xa.o" error message

Q: When I try to compile my WebObjects 4.5 application on a Solaris 2.6 system, I get the error message:

```
Link error, can't find Xa.o
```

My app compiles and links without this issue on other platforms. What's wrong?

This article has been archived and is no longer updated by Apple.
A: Some Solaris 2.6 distributions did not include the operating system package

```
System SUNWarc Archive Libraries
```

which is required by the WebObjects linker. The archive libraries are included in your Sun distribution and can be added to your system with the "pkgadd" command.

WebObjects 4.5: Preventing Zombie Processes on Solaris

Q: My WebObjects 4.5 application is running on a Solaris server; my database is running on a separate system. If the database shuts down, zombie processes are created on the WebObjects server machine. How can I prevent this?
This article has been archived and is no longer updated by Apple.
A: Add this line to the sqlnet.ora file on the Oracle client system:

BEQUEATH_DETACH=yes

The oracle executable will now catch the child signal from the SQLNet connection, preventing the creation of zombie processes. This value is set when the Oracle server is installed, which is why this issue does not occur if the WebObjects application and the Oracle database are installed on the same system.

WebObjects 4.5: Control-Dragging in Windows NT Project Builder

Q: On other platforms, I can control-drag files to sort them in the Project Builder file browser. This doesn't seem to work on Windows NT versions of Project Builder. How can I enable this feature on Windows NT?
This article has been archived and is no longer updated by Apple.
A: To enable control-dragging on Windows NT, type the following at a Bourne shell:

```
defaults write NSGlobalDomain NSModifierFlagMapping "{LeftControl=Command;RightControl=Control;LeftAlt=Alt;RightAlt=Alt}"
```

This allows you to use the the right control key (or any key you set to "Control") to control-drag files in Project Builder on Windows NT. You can also set this mapping in the Project Builder domain if you only want it to apply to Project Builder. Using NSGlobalDomain will apply it to all of the current user's applications.

For more information on customizing WebObjects' text system, see the TextDefaultsAndBindings documentation in the Programming Topics section of WOInfoCenter.

WebObjects 4.5: Sybase Client Libraries Available From Sybase

This article discusses how to obtain the Sybase Client Libraries for WebObjects 4.5.
This article has been archived and is no longer updated by Apple.
Beginning with WebObjects 4.5, Apple Computer, Inc. no longer distributes the Sybase OpenClient Libraries for Windows NT on the WebObjects CD. WebObjects customers must now contact Sybase directly to purchase the appropriate client libraries for development and deployment platforms. You should contact Sybase or see their website for the latest information. See technical document 75396, "**Sybase, Inc. Contact Information**".

This article supercedes the documentation distributed on the WebObjects 4.5 CD. The client library version referenced in the EOF release notes is compatible with both WebObjects 4.5 and WebObjects 4.0.1 installations.

WebObjects 4: Errors Creating the WebObjects.conf File

Q: When deploying a WebObjects 4 application on Windows NT or Windows 2000, I get an error message saying that the WebObjects.conf file could not be created.
This article has been archived and is no longer updated by Apple.
A: This message occurs if WebObjects can't write to the directory where it expects to write its temporary files. To fix this, open the Windows Registry Editor, REGEDIT.EXE. In the registry, find the directory HKEY_LOCAL_MACHINE\\SOFTWARE\\NeXT\\WebObjects\\Configuration.

There should be five entries in this directory: Default, CGI_BIN, DOCUMENT_ROOT, NEXT_ROOT, and TEMP. Make sure that the TEMP directory is set to a directory where WebObjects has write privileges. The entry should be formatted like:

TEMP "c:/inetpub/conf/"

Be sure to use forward slashes for the pathname, not backslashes.

TA45446_WebObjects_Slow_Netscape_Performance_on_Windows_.pdf

WebObjects 4.5: Slow Netscape Performance on Windows 2000

This article describes a known WebObjects issue with Netscape browsers on Windows 2000.
This article has been archived and is no longer updated by Apple.
When a Direct to Web application running on Windows 2000 is accessed using the Netscape browser (v4.72) running on the same machine, it takes a long time for pages to be returned. The Netscape browser appears to consume all available CPU time while loading the response to a form submitted with method=POST. The long delay returning pages is due to the application being starved for CPU time rather than being an issue in WebObjects. Possible workarounds are to run the Netscape browser on a different machine, or to use a different browser.

DAL 1.2: How to Get Listener Module for VMS 5.4

I am planning to upgrade our VAXCluster to VMS 5.4 and need a copy of the DAL listener module that supports the 5.4 password hashing algorithm. Does the DAL package that ships with PATHWORKS for Macintosh from DEC support 5.4? Or do I need a new listener? How do get a copy of the module?
This article has been archived and is no longer updated by Apple.
Note: Earlier versions of DAL were referred to as CL/1.

There is a compatibility problem with the new VMS 5.4 release and the CL/1 1.0 and 1.1 VAX/VMS servers. Due to changes in VMS password authentification in VMS 5.4, AppleTalk connections fail when made to the earlier versions of VAX/VMS Server (CL/1 Servers 1.0 and 1.1) running on a VMS 5.4 system. This is a problem with AppleTalk connections only; asynchronous connections do work. There is no workaround for the 1.0 and 1.1 versions.

DAL 1.2 is compatible with VAX/VMS 5.1 through 5.3. Compatibility with VAX/VMS 5.4 is shown below.

VMS 5.4 Compatibility

Async AppleTalk
----- ---------

CL/1 1.0,1.1 Yes No

APDA DAL 1.2 Yes No *

* If you have recently installed VAX/VMS 5.4 or are planning on upgrading to 5.4, please contact the Technical Answerline, so that we may send you a new DAL Listener module that is compatible with VAX/VMS 5.4. As of release 1.3 of DAL, VMS 5.4 is supported as part of the standard product.

When customers purchase Data Access Language, they have a card that they can send in for support on Technical Answerline for 90 days. After that, they can purchase a one-year Technical Answerline support. They can purchase this Technical Answerline contract from a dealer. Customers on a support contract may call the Technical Answerline to request for the DAL Listener module that works with VAX/VMS 5.4.

PATHWORKS: How to Create a System 6.0.7 Installer Disk

How can one create a PATHWORKS for Macintosh Installer Disk with System Software 6.0.7?

This article has been archived and is no longer updated by Apple.
The PATHWORKS for Macintosh Installer Disk is just like a normal System Software 6.0.7 startup disk with AppleShare Workstation software, so you can access to a VAXshare file server. All the PATHWORKS for Macintosh software is located on the VAXshare file server. The PATHWORKS Installer Disk works when your Macintosh is connected to the Digital network through LocalTalk and a router, or through an Apple EtherTalk NB card. EtherTalk software must be installed on this Installer Disk for this use.

A/UX 2.0: Double-Click Behavior and Locked Files

Sometimes A/UX fails to respond promptly to mouse clicks (presumably because the preemptive time slicer has preempted the task running my Macintosh window and has given the CPU to someone else).

So, for example, when I'm trying to edit a file name by clicking the name under the icon, I often find myself launching the software instead, because the Macintosh "double-click detector" thinks I double-clicked, when in fact I only clicked twice in the text field of the icon. In other words, the definition of "double-click" seems to be variable under A/UX.

This article has been archived and is no longer updated by Apple.

Although A/UX handles jobs based on a preemptive, time-slice basis, we can't reproduce the mouse double-clicking behavior that you described. In any case, here is the scenario of the mouse motion:

If the file is UNLOCKED and the mouse is pointed and single-clicked on the name of that file under the icon, the mouse symbol SHOULD change from arrow pointer to I-beam which lets you change the name of the file (the name is then highlighted). Then, when the mouse is double-clicked on the name, the word in the name is selected and allowed to change that word. When the mouse pointer leaves the name area, it becomes an arrow point.

If the file is LOCKED and the mouse is pointed and a single-clicked on the name of that file under the icon, the mouse symbol remains an arrow pointer which means the name of file can't be changed, because it was LOCKED. In this case, if the mouse is double-clicked on the name of the locked file, it will launch the program.

Check if the file to be renamed is LOCKED or UNLOCKED.

MacX 1.1: Visual Types Supported

Which visual types does MacX support--static gray, pseudo color, direct color? I have observed a response of static gray to a visual type query when using an RGB monitor Would the individual display (B/W rooted, rootless and Color rooted, rootless) return a different visual type when queried? How does it handle different monitors on the same system and the client application running across those different monitors?

This article has been archived and is no longer updated by Apple.

MacX, like all X11r4-based servers, supports all visual types on the 8-bit screens that make sense. This means that, given the right colormap, MacX can support or "fake" PseudoColor, DirectColor, Gray scale, StaticGray, StaticColor, and TrueColor. You can use xdpyinfo to see all of these visuals.

MacX: Arc-Drawing Algorithms

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

In terms of drawing algorithms, MacX has apparently optimized arc-drawing algorithms, but wide-line drawing seems to be extremely slow. I noticed this while working with mwm.

This article has been archived and is no longer updated by Apple.
You are correct. Much better arc drawing code is present in MacX than is present in many X11 servers. On machines that have a floating point unit (all Mac II-class machines, Macintosh SE, and Macintosh IIsi with FPU installed), MacX uses this hardware to achieve good arc-drawing performance. Without an FPU, MacX uses SANE to do its floating point, but it is still pretty fast. Thick lines are slow. Actually, pretty much the same arc-drawing code appears in MacX 1.0 as in MacX 1.1.

NCSA Telnet 2.3: Questions and Diagnosis

I have a two problems regarding Telnet. I have been using Telnet rev 2.2 and recently upgraded to Telnet 2.3, which is now using MacTCP 1.01. I am using a LocalTalk connection to a Kinetics FastPath IV rev J. I have not yet upgraded these units for Phase 2 AppleTalk yet. Every time I try to transfer a file using FTP from my Sun system to the Macintosh, it hangs my machine.

The other new error happens when I am doing a Telnet session--I get NCSA Telnet error #1, program unexpectedly quit. It is independent of CPU (I am using system 6.0.5 on all systems). The problem showed up when I upgraded to Telnet 2.3. Have you heard of any problems like this one?

This article has been archived and is no longer updated by Apple.

We haven't heard any problem like this. There are two versions of NCSA Telnet 2.3, one is Telnet without MacTCP, the other is Telnet with MacTCP. Here are some things to check:

* Make sure you're using the right version of NCSA Telnet 2.3. In this case, you must use NCSA Telnet 2.3 with MacTCP.

* Was MacTCP driver installed and configured properly?

* Was Kinetics FastPath software installed and configured properly?

* Try running "MacTCP Spy" from the Macintosh OS to see if MacTCP is up and running.

* From the Sun machine, try to use "ping", a generic UNIX network utility, to send an ICMP packet to the Macintosh machine to make sure they are talking to each other.

* Try to increase the NCSA Telnet 2.3 with MacTCP application memory size. This is done via Get Info.

Software that Compares Files after Copying (2/91)

When you do a regular copy on a Macintosh (drag a folder or file to another volume), does the Finder do any compare or verify in that command?

Is there any program that can compare two different files to see if they are totally equal? I need a program that verifies that a copy of a file is an image of the original.

This article has been archived and is no longer updated by Apple.
After a copy, the Finder does minimal checking to see if any errors were logged during the copy or verify. It doesn't do a checksum, or any byte-for-byte comparisons of the file.

As for file comparisons, the Hard Disk Jockey disk utility from FWB lets the user copy and verify (among other things) files on disk.

The Macintosh Programmer's Workshop (MPW), available from APDA, comes with two utilities for comparing files:

* Compare compares the lines of two text files and writes their differences to standard output. Options are provided to compare a specific column range in each file, to ignore blanks, and to ignore case.

* ResEqual compares the resources in two files and writes differences in type, identifier, size, or contents to standard output.

LaserWriter IINTX: Hard Disks Can Be Cloned under A/UX (11/94)

I have attached to a LaserWriter IINTX a hard drive that is apparently bad. Because there is another unit which is still in good condition, is there a way to transfer the contents of the good hard disk to the other?

This article has been archived and is no longer updated by Apple.
We don't have a utility specifically designed to copy or back up font info stored on LaserWriter hard disks, but you can clone the disk under A/UX.

* Connect two drives of the same size to an A/UX system.

* Set the SCSI address of the source drive to 5 and the target drive to 6.

* Boot A/UX and login as root.

* At the command line, type:

dd if=/dev/dsk/c5d0s31 of=/dev/dsk/c6d0s31 (do not type the #)

The process will take about 1 minute per megabyte of disk space. When it is complete, type:

sync;sync;sync

Log out and shut down the system. Re-connect the disk to the LaserWriter, power-up and print.

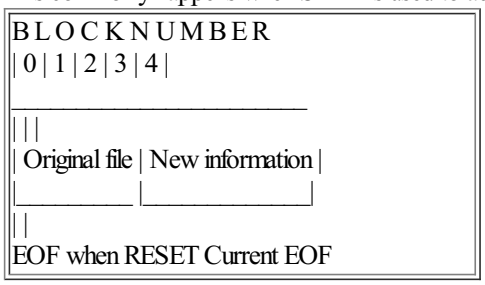
Pascal II: SEEK

This information applies to Pascal 1.1.
This article has been archived and is no longer updated by Apple.
When you SEEK to a record that has been added to the file since the last RESET, often it either takes a very long time to find the record or else Pascal stops with a SYSTEM FAILURE.

This commonly happens when SEEK is used to access a new record from a file extended with PUTs. Further operations on the file may trash it.



In this example, a SEEK to a record in the last half of block 2, block 3 or block 4 will cause problems.

If you must extend a file and then SEEK to one of the new records, RESET the file before doing the SEEK.

DAL Server for A/UX: Availability

Is there a version of DAL Server available for A/UX?
This article has been archived and is no longer updated by Apple.
NOTE: As of December 1993, Independence Technologies, Inc. (ITI) took ownership of the DAL technology. Contact ITI for current product information.

Data Access Language (DAL) 1.3 will work with A/UX 2.0 or 2.0.1. Connections can be made via asynch or TCP/IP but not AppleTalk because A/UX 2.0 and A/UX 2.0.1 don't support ADSP. DAL 1.3.6 supports A/UX 3.0 and ADSP is supported to A/UX as of that release.

Oracle, The Ask Group, Inc./Ingres Products, and Sybase have announced a server that runs on an A/UX 2.0 platform.

On AppleLink, you can find contact information on a company mentioned in this article by clicking the "Library Index" button in the lower-center of the Tech Info Library search window, then opening the "Third Party Company Directory" folder.

LaserWriter: Deleting Pages from RAM

After the LaserWriter prints a document, does an image of the document remain in the LaserWriter's RAM? If so, when does it get removed?
This article has been archived and is no longer updated by Apple.
After the LaserWriter gets the image of the page in memory, the PostScript command "showpage" is called to print the page. The "showpage" command looks up the value in "#copies" to determine how many copies to print and then prints that number of pages. Once the printing is completed, the "showpage" command does the equivalent of the "erasepage" and "initgraphics" PostScript commands.

The "erasepage" command erases the entire image in the LaserWriter memory by painting it with gray level 1, which is normally white. The "initgraphics" command resets many of the graphics states to their default values.

For more information on "showpage", "erasepage", and "initgraphics", see pages 238, 161, and 184, respectively, of the "PostScript Language Reference Manual."

Multiplan: Doesn‘t Run on the Macintosh Classic

I bought a Macintosh Classic to replace a Macintosh Plus. I am using System Software 6.0.7 and Multiplan version 2.4. Multiplan bombs on the Macintosh Classic. You can start the program, but when you try to enter anything in a cell, it gives an error message saying there is an address error, and you have to restart the Macintosh. Could the problem might be that Multiplan just won't work under System Software 6.0.7?
This article has been archived and is no longer updated by Apple.
The latest version of Multiplan is Multiplan 1.1, and it doesn't work on the Macintosh Classic. Multiplan 1.1 has not been sold in the U.S. since 1986.

Microsoft Technical Support told us that the latest version of System Software that Multiplan 1.1 was tested with is System Software 2.0 which used System 4.1 and Finder 5.5. Microsoft no longer supports Multiplan and suggests upgrading to Excel.

ROLMphone 244PC Phone Controller

Are you folks aware of a Macintosh product that controls a ROLM 244-PC phone? I am looking for something with the same feature set as IBM's "Personal Telephone Manager"

This article has been archived and is no longer updated by Apple.

There is a Macintosh ROLM 244-PC phone "control" application:

The ROLMphone 244PC is a smart, voice and data-communications telephone that links personal computers to the ROLM 9751 CBX and ROLM CBX II family of voice/data controllers. It combines a digital ROLM telephone with data communications features that support the "AT" intelligent modem command set. The ROLMphone 244PC also includes a documented programming interface (API) that lets programmers design specific, telephone-enhanced applications in areas like outbound dialing, inbound answering, telephone management, and integrated voice/data applications. The documented ROLMphone 244PC API lets a user write customized applications.

You may wish to contact ROLM's direct sales and support team for a copy of the API documentation and write your own control program.

Document Time-Monitor Software Needed

I have a newspaper running four Macintosh IIcx computers on a AppleShare Macintosh SE/30 server and printing to a Birmy Imagesetter with its own spooler. The production manager needs to track the documents off each workstation, documenting how long was spent on each document and its deadtime (the amount of time the document was open but no keyboard or mouse action took place). We've looked at Macintosh-In-Use, but it only totals up all the deadtime from that workstation, and doesn't seem to be able to apply it to the individual document.

This article has been archived and is no longer updated by Apple.
We don't know of a product that will do the above. One developer we mentioned to you may design and ship a product this year somewhat along these lines, but has not yet started on it or determined its feature set.

If anyone else knows of a document time monitor, please send in whatever details you have to TECH.COMM.

A/UX 2.0: CmdShell vi Repeat Key Problem on Macintosh IIfx

I've noticed another bug in A/UX 2.0, but only on Macintosh IIfx. To see it, do these steps:

1) Open a CommandShell Window, and in this window open a big text file (/FILE for instance) with the vi editor.

2) Type some text and all seems to be okay. But sometimes, you will notice that if you use a key with auto-repeat mode, the auto-repeat mode will stop without any reason (for example, while holding down an arrow key).

If you want the auto-repeat function to start again, you must hit the release the key and press it again, or you must move the mouse outside a window (in this last case, you are not obliged to release the key).

This article has been archived and is no longer updated by Apple.

We have verified the symptom of the repeat key performed in vi under CommandShell with a Macintosh IIfx running A/UX 2.0. This strange behavior on the repeating key will be sent to A/UX engineering for further investigation.

For your information, here are two scenarios. In A/UX 2.0, both the mouse pointer and the current keyboard cursor are coexistent. However, in A/UX 2.0.1b2, the mouse disappears from the desktop as soon as the keyboard is activated.

A/UX and Apple CD-ROM: Commando "mount" Minor Bug (8/94)

I am trying to mount a CD ROM under A/UX, using Commando to build the command. When you select "Read Only" mounting options for the "mount" command, it returns

mount -r -o rw

If you click the appropriate option, does the -r override the rw option?

This article has been archived and is no longer updated by Apple.
The Commando returns "mount -o rw" after choosing "Mount specified filesystem" because the default option for "mount" is read/write. The Commando produces "mount -r -o rw" after choosing "Read Only".

Because "-r" is identical to "-o ro", the "Read Only" operation SHOULD override the previous default (rw) option. However, The "-o rw" can be changed to "-o ro" by selecting "Read Only" from the "Other options" button.

A/UX AppleTalk Network Configuration (8/93)

I have a problem with my A/UX 2.0 network configuration. My network is okay when working with MACpartion, but when I start up A/UX, all the zones disappear. My configuration is:

Macintosh IIci with 8MB
External LA CIE 80MB Hard Disk
Apples NB Ethernet board

This article has been archived and is no longer updated by Apple.
Based on the fact that the zones disappear, we suggest you consider the following diagnostic questions:

* Is AppleShare server and/or PrintServer and/or Apple Internet Router on the AppleTalk network based on AppleTalk Phase 2? A/UX 2.0 does not support AppleTalk Phase 1.

* Is "appletalk" configured within A/UX 2.0 kernel? Use "module_dump /unix" to verify it.

* Is "appletalk" currently running? Use "appletalk -s" to see the status. Use "appletalk -d" to bring AppleTalk network DOWN, and use "appletalk -u" to bring the AppleTalk network UP.

* Make sure the interface is properly selected; this is specified in the /etc/appletalkrc file.

* Refer to Chapter 6 of "Administering AppleTalk" in A/UX Network System Administration for more detailed information.

The message "appletalk: No such file or directory" from the "appletalk -u" command output is a strong indication that the /dev/appletalk directory and/or its sub-directories and files are probably missing or corrupted. Normally, the /dev/appletalk directory should include as follows:

```
total 4
drwxr-xr-x 2 bin bin 512 Dec 7 10:07 ddp
drwxr-xr-x 4 bin bin 512 Dec 6 18:01 lap

appletalk/ddp:
total 0
crw-rw-rw- 1 bin bin 12, 16 Jan 15 16:15 socket

appletalk/lap:
total 4
drwxr-xr-x 2 bin bin 512 Dec 7 10:07 ethertalk0
drwxr-xr-x 2 bin bin 512 Dec 7 10:07 localtalk0

appletalk/lap/ethertalk0:
total 0
crw-rw-rw- 1 bin bin 15, 0 Dec 7 10:07 control

appletalk/lap/localtalk0:
total 0
crw-rw-rw- 1 bin bin 17, 0 Dec 7 10:07 control
```

If the /dev/appletalk directory is causing the problem, do these steps:

1) Run a file system check on the Root file system: fsck /dev/dsk/c?d0s0

2) De-install the appletalk module from the kernel: newconfig noappletalk

3) Re-install the appletalk into the kernel: newconfig appletalk

After re-installing appletalk, the appletalk modules, the /dev/appletalk directory and its sub-directories and files will be correctly re-created.

Apple Tape Backup 40SC Description, Compatibility (Discontinued)

This article describes the Apple Tape Backup 40SC.

This article has been archived and is no longer updated by Apple.
The Tape Backup 40SC is a block-type device: data is written to, and read from, the tape cartridge in blocks. The controller module provides all data handling functions for SCSI bus transfers and tape cartridge Read/Write module controls, Read-Write head positioning, end sense, and analog-to- digital, digital-to-analog (ADC/DAC) signal conversion for the tape cartridge. The drive and Read-Write modules perform their functions under the direction of the controller module.

Writing to the tape unit begins with the user's command to back up a storage device such as a hard disk. Backup utility software loaded into the Macintosh receives this command and begins transferring data from the storage device to a range of Macintosh main memory. The software then passes control and the address in main memory of the data being transferred (buffer address) to the Macintosh SCSI firmware.

Using standard SCSI commands, the SCSI firmware gives the controller module the logical address to write the incoming block to the tape unit. The controller module translates the logical address to a physical address on the tape, and sends the Read-Write and drive modules commands to position the Read-Write head and activate the tape transport. The incoming data blocks are buffered in the controller module during this translation, but then are passed to the Read-Write module for writing through the control module interface. The Read-Write module then performs the actual write operation according to the commands sent to it by the controller module. The controller module uses the standard SCSI protocol to tell whether the write was successful.

Reading from the tape backup unit begins when the user issues a command to recover a backup file. The backup utility software receives this command and sets up a range of Macintosh main memory (a buffer) to receive the incoming file. The software then passes control (and the buffer address in main memory) to the Macintosh SCSI firmware.

To read from the tape unit, the Macintosh SCSI firmware sends the controller module the logical address of the target block, using the standard SCSI commands. The controller module translates the logical address to a physical address on the tape cartridge and sends the Read-Write and drive modules the commands to position the Read-Write head and activate the tape transport. The outgoing data blocks are passed to the controller module through the control module interface. They are buffered in the controller module and then passed to the SCSI controller for output onto the SCSI bus. The controller module acknowledges correct (or faulty) execution of the read operation to the Macintosh software through the standard SCSI protocol.

The SCSI firmware in the Macintosh receives the data sent by the controller module and writes it to the previously allocated buffer. The controller module, however, acknowledges correct operation as soon as it has passed the data blocks on to the SCSI bus, regardless of the success or failure of the SCSI firmware's side of the exchange.

IMPORTANT COMPATIBILITY NOTES:
* The Tape Backup 40sc is compatible with type DC 2000 tape cartridges.
* The bundled software included with the Tape Backup 40SC is Tape Backup 40SC 2.0.1, which is INCOMPATIBLE with System 7 and later.
* Apple recommends using third-party backup software with the Tape Backup 40SC. Some products that work with the Tape Backup 40SC are Retrospect and Retrospect Remote from Dantz Development Corp., and FastBack Plus from Fifth Generation Systems.

Plotter: Sharing on AppleTalk Network

Do you know how to share an HP Plotter between Macintoshes and PCs on an AppleTalk network?
This article has been archived and is no longer updated by Apple.
We found a Macintosh-only solution from Palomar Software. PLOTTERgeist is a Chooser-selected driver for plotters connected to a network via Shiva's NetSerial product. You could work around the no-PC limitation by connecting the plotter to an A/B switchbox connected to the NetSerial on one port and a peripheral-sharing switchbox (Black Box has them) on the other.

AppleShare PC: NDIS Compliant? (11/94)

Is AppleShare PC NDIS compliant? I would like to run AppleTalk and TCP/IP protocols through the LocalTalk PC Card at the same time.

This article has been archived and is no longer updated by Apple.
The Microsoft/3Com specification known as the Network Driver Interface Standard (NDIS) specifies software requirements and its interface to hardware and protocol stacks for PC network drivers. It is, therefore, very similar in purpose to our Open Data-Link Interface specification (ODI) which we co-developed with Novell.

However, each of these specifications detail similar requirements in very different ways. An application written to one standard cannot work with drivers based on the other. The two specifications are essentially competitors in the PC-network, driver-architecture world.

Because of this, a protocol stack based on one standard cannot coexist on a network card with a protocol stack for the other standard. This is the unfortunate side effect of two competing standards. A user must use one or the other set of software at one time. Switching between them generally requires rebooting the computer.

Because AppleShare PC 2.0.x is based on the ODI specification, software based on NDIS cannot use a network interface card while AppleShare PC is using it. This prevents an NDIS based Telnet application from concurrently using the same network card as AppleShare PC.

We don't know of any ODI compliant TCP/IP software that can coexist with AppleShare PC, but we'll submit this to product management as an enhancement request. We'll also submit it to Farallon product management, because they're now taking over the AppleShare PC product.

TA45472_HyperCard_FTP_and_Telnet_(TIL07043).pdf

HyperCard, FTP, and Telnet

Do you know of any XCMDs or XFCNs that use MacTCP or other TCP/IP drivers which let HyperCard do a Telnet or FTP session?

This article has been archived and is no longer updated by Apple.
The HyperCard MacTCP Toolkit version 1.0 is available from APDA and provides the functionality that you want. Here is the description from the APDAlog:

This toolkit contains XCMDs and source code for using HyperCard with MacTCP. Included is a sample stack for reading "netnews" and a documentation stack. MacTCP is software that allows developers to create Macintosh applications for networking environments that use TCP/IP protocols, a widely used standard for networking heterogeneous systems.

We haven't heard of a stack that supports the Telnet protocol.

There is an FTP client stack, called HyperFTP, written by Douglas Hornig of Cornell University. The latest version is available for anonymous FTP download at elroy.cit.cornell.edu (128.253.232.14).

A/UX: Printing to Serial LaserWriter Plus (8/94)

I have a Macintosh IIfx with 8MB of RAM and a 160MB hard drive running A/UX. I want to attach the Macintosh IIfx to a LaserWriter Plus and print to it serially using the printer port on the back of the Macintosh.

I've set the speed of the LaserWriter Plus to 9600bps, set up the print queue, enabled all relevant print daemons, and I've used the setport command to establish the speed of the printer port.

I've used a direct RS/232 cable (Hayes Modem Cable), 2 LocalTalk connectors, and 2 PhoneNET connectors, and I get the same results: the printer flashes its Ready lights, but never prints anything.

I made it work using AppleTalk. I've tried using the Enscript utility to establish direct communication with the print and am successful, but when I try to establish communication with the PostScript interpreter, I get garbage. Is this an A/UX issue or is it related to the serial ports of the Macintosh IIfx--or both?

This article has been archived and is no longer updated by Apple.
We have never used a direct RS-232 cable (Hayes Modem Cable), 2 LocalTalk connector, and 2 PhoneNET connectors to connect a LaserWriter Plus to a Macintosh. For a direct connection of a Macintosh to a LaserWriter Plus, We recommend you use a Mini-DIN-8 Male to DB-9 Male cable (cable number 590-0551, Apple finished goods number M0196). Furthermore, to make sure the connection is working, you can use the "cu" command to verify it.

We are not quite sure what you mean by "established communication with the PostScript interpreter". To print a PostScript format file directly, the %! symbols must be the first two characters on the first line of the file so that the rest of the file will be treated as the PostScript format by the PostScript printer.

DAL: Response Time Via Modem

Do you know what is the response time for a simple DAL query to the host through a 2400-baud modem? Do you know what is the response time for a simple DAL query to the host through AppleTalk tunneling?
This article has been archived and is no longer updated by Apple.
It is difficult to provide any hard number because the response time varies so much depending on the environment. There are a number factors that can affect response time:

* Network traffic

* Host CPU model and its current user load: lack of system resources like memory, disk space, and CPU power. Too many users trying to update or read the same records at the same time can cause locking problems.

* Condition of communications line

* Macintosh model

* Database brand

* Database design: Bad design can make finding or updating certain records take a long time.

* Operating system set up

* Programs

Additionally, a DAL query, though simple, can result in one or many records to be selected. Depending on the machine's host load, a 2400-baud connection will work. For DECnet tunneling, we recommend a line speed of 56K or faster to achieve reliability and good performance.

MacX: How to Use It in a DECnet Environment (1/95)

Regarding the use of MacX in a DECnet environment:

1) A DECnet driver is needed for the CommToolBox.

2) This driver does a translation from TCP/IP to ADSP.

3) The driver is available only from DEC, as part of PATHWORKS.

This article has been archived and is no longer updated by Apple.
1) You need a DECnet/Mac driver in the System Folder, and a DECnet Tool in the Communications Folder. There is also a DECnet Control CDEV, that shows DECnet traffic statistics, and allows turning Network State on or off.

2) The DECnet driver does not translate TCP/IP to ADSP. It uses DECnet protocol to communicate with the VAX host. Another tool, the AppleTalk-DECnet Connection Tool establishes a connection to a DECwindows application through the AppleTalk/DECnet Transport Gateway. This one uses ADSP connections.

3) The DECnet Connection Tool and driver are included with the PATHWORKS for Macintosh package. Alisa also stated that their TSSnet software supports MacX connection over DECnet. For contact information, search the Technical Info library under "Alisa."

Accelerator Boards: Using Virtual Memory

Can I get virtual memory with 68000 machines and 68020 machines without a PMMU by adding a 68030 accelerator board? If so, are there any repercussions I should know about?

This article has been archived and is no longer updated by Apple.

Yes, one way to get virtual memory with 68000 machines and 68020 machines without a PMMU is to add a 68030 accelerator board. Warning: adding a 68030 accelerator board to your 68000- or 68020-based system does not guarantee that one of the third-party virtual-memory products will support the upgrade you have added.

If virtual memory support is your goal, verify with the board manufacturer that their product works with your virtual-memory products. Likewise, check with the virtual-memory product's manufacturer to verify that their product works with your 68030 accelerator board.

Apple IIc Plus: No 40-Column Mode in Access II

I am using an Apple IIc Plus and Apple Access II. The Volume Slide Control on the keyboard for the Apple IIc Plus replaces the 40- or 80-column mode switch found on the original Apple IIc.

Typing PR#3 for 80-column mode and PR#0 for 40-column mode works when in ProDOS, but when using Apple Access how can I switch between 40- and 80-column mode?

Aren't both 40- and 80-column modes supported in Apple Access II?
This article has been archived and is no longer updated by Apple.
Apple Access II does not support 40-column mode on the Apple IIc Plus. The software detects that the 80-column mode is available and wants to switch the system into that mode. There is no workaround.

Apple IIe/IIGS: Connecting to IBM Host via 3708

I would like to access an IBM host via an Apple IIe or Apple IIGS for services like PROFS. There is a 3708 in some way attached to the host, and I can log in with an emulator through this device. I'm having a problem with keyboard mapping (particularly the PF keys).

This article has been archived and is no longer updated by Apple.
The 3708 is a protocol converter that converts, among other things, a terminal's ASCII character set to the host's EBCDIC character set. You don't mention what terminal emulator is being used on the Apple IIGS, but we suspect it is a VT52, VT100, or similar type of emulator.

Regardless, you'll need to verify that the terminal emulator type you are using is among those supported by the 3708. Check the "IBM 3708 Planning Manual" for the list of non-IBM ASCII display terminals it supports.

Even though terminal packages may not specifically state that they support IBM host communications and PF keys, many emulators can send the specific escape or command key sequences that are recognized and remapped by the controller into PF keys. For instance, Apple Access II's key sequence Esc-1 is remapped by many protocol converters to a PF1, an Esc-$ to PF16, and so on.

When using a general-purpose terminal emulator, like a VT100 emulator, you need to identify which ASCII key sequences map to PF keys, after you satisfy the general connection requirements like handshaking issues. Check the 3708 documentation for the ASCII to EBCDIC mapping. To determine if an emulator will send the specific ASCII key sequences, check the emulator's manual or contact the manufacturer. You too could use a datascope analyzer to determine what the appropriate character combinations are.

In terms of general information, the 3708 Network Conversion Unit is a ten-port, compact, desktop, protocol converter. It enables asynchronous ASCII terminals or personal computers with asynchronous ASCII communications capability to connect to and be compatible with one or multiple SNA host and non-SNA host systems. The user of an asynchronous ASCII terminal can access host applications that support 3270 displays and printers, Network Terminal Option devices, and applications that support the actual terminal type.

A/UX 2.0: Missing /dev File

After installing a brand new copy of A/UX 2.0, I've discovered that I'm missing a needed device file: /dev/dsk/c0d0s3.

I've used HDSetup to partition my internal HD160 SC drive (SCSI 0), and selected partitioning that would allow a 40MB Macintosh partition, Standard A/UX partitions, and the rest as "Unreserved 1" Slice 3. Without this device, I can't set up that final partition on my disk unless I repartition.

Is it possible to modify an existing device file to create this missing one? How would I do this?

This article has been archived and is no longer updated by Apple.

```
The missing device file /dev/dsk/c0d0s3, for example, can be created by the
"mknod" command:

   mknod /dev/dsk/c0d0s3 b 24 3
   chmod 600 /dev/dsk/c0d0s3
   chown bin /dev/dsk/c0d0s3
   chgrp bin /dev/dsk/c0d0s3

Note that 24 is the major device number, 3 is the minor device number for
/dev/dsk/c0d0s3, and b indicates a block device type.  Of course, you have
to be "root" to do it.

The "pname" command seems to do the same thing.  It will automatically
create the file in the /dev/dsk directory, if c0d0s3 doesn't exist. In your
case, for example, pname -c0 -s3 "Unreserved 1".

A/UX 2.0: Input during Login Session

If I have something in my login file, like a question about setting the variable term with the A/UX login, I can answer but I can't see what I am typing. Is there a way to have a window with the question in it?

This article has been archived and is no longer updated by Apple.

Since A/UX Finder 32-bit environment was selected as a default Login Session, and the Login process (not part of CommandShell process) was handled via the /mac/bin/mac32 process, all output messages (from .profile or .login or .cshrc or .kshrc file) are disabled by the mac32 environment. We know of this symptom.

There are, however, two ways that let you view and answer the question asked in the shell script: the "Console Emulator" Session and "Initial command" dialog box.

Console Emulator Session

Use "Console Emulator" session. This lets regular UNIX input or output (usually specified in the .profile or .login or .cshrc or .kshrc file) be viewed on the Console display.

1) Select "Console Emulator" as the Session Type.

2) Login into Console Emulator mode. All the questions asked in the .profile or .login or .kshrc file will be displayed.

3) Issue the "mac32;screenrestore" or "mac24;screenrestore" command to go to Macintosh 32-bit or 24-bit environment.

Or you may insert the "mac32; screenrestore" or "mac24;screenrestore" command at the end of your .profile or .login or .kshrc file to automatically go to MultiFinder environment.

4) Select "Logout" from MultiFinder environment to get back to the "Console Emulator" mode.

5) Issue the "exit" command from the "Console Emulator" mode to get back to the Login Dialog session.

The Initial Command

Use the "Initial command" dialog box from the "Active Window Settings" menu:

1) Within a CommandShell window, select the "Active Window Settings" item from the "Preferences" menu.

2) Put in any command you want to execute at log-in time into this window. For example:

sh /.cmdshrc

where /.cmdshrc is the shell script file to be executed as soon as you log into this window.

3) Click OK.

4) Select the "Save Preferences" item from the "File" menu to save the settings. The .cmdshellprefs file will be created in the user's home directory.

Aristotle Menu Setup Problem: Check Access Privileges

We are having problems with menu access using Aristotle. The server is a Macintosh SE/30 4/80, running the latest System software (GS/OS 5.0.2) and the proper Apple II Setup.

The menu setup that we are using lets two of the teachers have set their own menus up so that they can go into student menu Administration with a menu choice of their own. One teacher doesn't see that choice; he can only see his two classes. The other can't see one class, but sees administration.

What could be wrong in the setup?
This article has been archived and is no longer updated by Apple.
The typical issue that causes this type of problem relates to folder access privileges.

The first teacher's access privileges are probably not set for access to the Menu Management program's folder, while the set for access to his two classes' folders. The second teacher's privileges seem to be set for access to the Menu Management's folder, while the class folder's access is probably not permitted. This has been the only way we have been able to duplicate the situation you describe.

HyperCard 2.0: Sound Changes

I have developed a "Vocal Communicator" stack that takes advantage of MacinTalk (Apple, Jan. 1 1983) and several XCMDs and XFCNs from HyperMacinTalk v1.0 (Copyright 1987, by Dennis C. DeMars). This stack worked perfectly on my Macintosh SE/30 under System 6.0.5 and HyperCard 1.2.5. With it, a mute person can answer questions and build sentences to be spoken aloud by the Macintosh. After I upgraded to HyperCard 2.0, all it would do was beep, or remain tied up and silent for the length of time that should have been spent "talking."

Is there something about HyperCard 2.0 that makes it incompatible with existing XCMDs or XFCNs?

This article has been archived and is no longer updated by Apple.

HyperCard 2.0 has changed the way XCMDs and HyperCard interact when using the sound capabilities of the Macintosh. Specific callback procedures have been added that XCMDs (and XFCNs) can use to signal HyperCard when they want control of the Macintosh's sound channels. It is likely that XCMDs using sound will need to be modified to work properly with HyperCard 2.0.

Macintosh Portable: Modem Switches Explained

Can you tell me what the switches on the Portable modem are used for?

This article has been archived and is no longer updated by Apple.
You localize the Macintosh Portable Modem through the use of an external line adapter (DAA) that plugs into the generic modem board (installed through the back panel).

There is a different DAA whose hardware complies with the different country regulations and which identifies itself to the main board, thereby enabling country-compliant pieces of firmware to control the modem ("automatic communication parameters configuration").

So, the purpose of the two switches is to provide four adjustable transmit levels. They are set in the same position at the factory for all countries. Transmitted levels comply with each country's regulation.

Since that time, a variety of developers have introduced products which provide the external video functionality customers require. For that reason, Apple decided not to offer a video adapter.

Customers in need of external video support have a wide range of products to choose from, including:

Sayett Technology's DataShow, an overhead viewplate that connects directly to the Portable's Video Out port

Aura System's ScuzzyGraph II, which enables customers to use the Macintosh Portable with a color monitor

Generation Systems' Portable Publisher, which lets Portable users take advantage of the Apple High Resolution Monochrome Monitor, Portrait Display, and Two-Page Display.

The above is a sample of the products and capabilities currently available to Macintosh Portable customers, and we anticipate other third-party video product announcements.

SYSTEM.CHARSET is used by the WCHAR and WSTRING procedures in Turtlegraphics to write textual information on the High-Res Graphics screen.

This article has been archived and is no longer updated by Apple.

It's a file of 1024 bytes, arranged in a sequence of 128 X 8 bytes in order to represent the ASCII character set. Each character is drawn from bottom to top; e.g., byte 0 is the bottom line of dots in the character. Drawblock uses these characters, so they should be accessed and treated as any other drawblock unit.

Network Troubleshooting: Symptoms & Causes

Troubleshooting a network can be much more difficult than troubleshooting a single piece of equipment. This is because many devices might be involved. Because of this, you should use a systematic approach to isolating and resolving the issue.
This article has been archived and is no longer updated by Apple.
Below is a list of possible symptom/cures to be referenced when troubleshooting network problems. The list is based on LocalTalk, Ethernet, Token Ring, and Star networks--but can be adapted to other topologies. If you are a service provider, additional information can be found in Apple Technical Procedures. In addition, there are other articles in the Tech Info Library that may assist you.

Missing Device Issues
Symptoms:
Can't access file server.
Can't access printer.
Can't access another zone on the network.
Can't access another network.

Possible causes:
Break in connector.
Broken or damaged pins on connector box.
Device turned off.
Cables severed or damaged.
Disconnected cable extenders.
Network interface card damaged, missing, or not installed properly.
System software versions not consistent across the network.
Incorrect printer or other device drivers.
Appropriate cdev and/or adev missing or not in System folder.

Token Ring:
MAU not connected.

Bad MAU port.
Ring In/Ring Out bad or not connected.

STAR:
Star Controller turned off, not plugged in or is malfunctioning.
Wires not punched down or punched down correctly.
Punchdown block not connected to Star Controller.

Ghosting Issues
Symptoms:
Network device appears and disappears in the Chooser.

Possible causes:
Loose connector.
Damaged or obstructed cable.
Improper termination.
Loose cable extenders.
Maximum cable length exceeded (check user manual).
Maximum number of nodes exceeded.
Electro-magnetic interference.
Network not designed properly.

Performance Degradation
Symptoms:
Slow printing
Slow file transfer
Network appears to be dead.

Possible causes:
Maximum number of nodes exceeded.
Excessive traffic.
System software versions not consistent across the network.
Virus.

File Folder Access
Symptoms:
Can't see files or folders.
Can't open files or folders.
Can't drop files or folders into drop folder.

Can't change file or folder name.
Can't move file or folder.

Possible causes:
Access privileges set incorrectly.
Files or folders locked.

HyperCard: Converting Stacks Macintosh <^> Apple IIGS (5/91)

This article describes HyperMover 1.1, a software tool for converting stacks between Macintosh HyperCard and HyperCard IIGS.

This article has been archived and is no longer updated by Apple.
Because of the differences between the Macintosh and the Apple IIGS, stacks created on one computer do not run directly on the other. HyperMover makes it easier and faster to convert stacks between the Macintosh and the Apple IIGS. HyperMover will be available from user groups and on-line services.

HyperMover 1.1 includes two stacks: Macintosh HyperMover and HyperMover IIGS.

MACINTOSH HYPERMOVER

Macintosh HyperMover analyzes a Macintosh HyperCard stack, then creates a folder containing information that HyperMover IIGS can use to create an equivalent stack for use on the Apple IIGS.

* HyperMover works on all Macintosh models capable of running HyperCard. It requires HyperCard 1.2.5, or HyperCard 2.0v2 or later.

* HyperMover may require up to 2MB RAM to dismantle or rebuild stacks. If you are running HyperCard under MultiFinder, allocate at least 1600K to HyperCard. Large stacks with many objects or sounds may require more memory.

* Disk space: HyperMover needs 1.5 to 5 times the size of the original stack.

HYPERMOVER IIGS

HyperMover IIGS analyzes a HyperCard IIGS stack, then creates a folder containing information that Macintosh HyperMover can use to create an equivalent stack for use on the Macintosh.

HyperMover IIGS requires:

* HyperCard IIGS 1.0 or later.

* System Software 5.0.4. or later.

* IIGS ROM 01 and ROM 03.

* 1.5MB RAM for small stacks, 2MB for most stacks.

* Disk space: 1.5 to 5 times the size of the original stack. In general, Macintosh stacks rebuilt on the Apple IIGS will be slightly larger than the original stack, because HyperCard IIGS supports color paint, which takes up more disk space.

TRANSFERRING THE FILES

After dismantling a stack, you must transfer the files HyperMover creates. This can be done either with Apple File Exchange or an AppleTalk network.

If you use a network, both the Macintosh and the Apple IIGS must be physically connected and logged on to a common server. Simply drag the folder that HyperMover created on one computer to a location on the server that you can also access from the other computer.

If you use Apple File Exchange, you must format as many disks as needed to contain the converted files. After formatting the necessary number of disks, use Apple File Exchange to transfer the folder containing the converted files. The files can be transferred in two or more groups if the contents of the folder total more than 800K and are combined into one folder.

When converting from Macintosh to Apple IIGS, the text file with the same name as the dismantled stack may not be a legal ProDOS filename; if this is the case, simply rename the file to a legal filename. Do not rename any of the other files in the folder.

DIFFERENCES BETWEEN STACKS

Because the Apple IIGS and Macintosh differ significantly in hardware, some aspects of a converted stack will not be identical to the original. HyperMover will pre-scan the original stack and warn the user of features, such as XCMDs and XFCNs, that will not be converted.

Graphics

The most noticeable difference between the original and the rebuilt stack will be in the graphics. The Apple IIGS and the Macintosh have different screen sizes (320x200, 4-bits per pixel; and 512x342, 1-bit per pixel). Therefore, graphics moved between the two systems need to be modified to fit and display properly.

This is handled by HyperMover in several ways:

* Macintosh graphics to the Apple IIGS. HyperMover contains two algorithms for scaling graphics from Macintosh to Apple IIGS screen resolution. The first routine is best used for line-art. The second is preferable for heavily dithered graphics such as those created with HyperScan.

* Apple IIGS graphics to the Macintosh. Moving graphics this direction involves reducing the number of colors available per pixel from sixteen (Apple IIGS) to black-and-white (Macintosh). At the same time, however, the picture must be scaled up from 320x200 to 512x342. This results in more pixels being available to simulate the colors lost during dithering.

Screen Coordinates

Just as pictures must be scaled to fit the destination card size, buttons and fields must also be scaled so that they appear in the correct locations on the destination card. However, buttons and fields are objects and can be scaled with no distortion.

Scripts

Because of the differing screen sizes, scripts converted from one system to the other will require modification to function properly if they rely on specific screen coordinates.

Scripts that rely on features specific to one system, such as the color properties of HyperCard IIGS or specific commands in Macintosh HyperCard 2.0, will also need to be modified to work correctly.

Animation Sequences

Animation sequences that use system icons and refer to them by ID will need to be modified after the stack is converted.

Machine-Specific Properties

Properties specific to HyperCard IIGS, such as button families and sharedText on the Apple IIGS will not be preserved in stacks converted to HyperCard 1.2.5. Conversion of HyperCard IIGS to HyperCard 2.0 will retain those properties that are common to HyperCard 2.0 and HyperCard IIGS.

Similarly, varying card sizes in HyperCard 2.0 will not be preserved in stacks converted to HyperCard IIGS.

WHAT HYPERMOVER CAN AND CANNOT DO

HyperMover can:

* Create scaled representations of pictures.

* Convert Macintosh sounds to Apple IIGS sounds, and vice versa.

* Transfer all HyperCard objects--including backgrounds, cards, buttons, and fields, and their attributes.

* Convert and scale Macintosh icons and cursors to Apple IIGS icons and cursors.

HyperMover cannot:

* Convert external commands and functions (XCMDs and XFCNs).

* Fix scripts that depend on specific screen coordinates.

* Alter scripts that rely on features specific to one machine.

* Maintain the ordering of buttons in relation to fields.

Non-Postscript Printers: Solution to Printing Large Characters

I'm having a problem writing large characters on a Personal LaserWriter SC. Printed characters larger than 18 point are being cut off near the bottom. For example, if an "f" is printed, most of the part below the crossbar is missing.

This article has been archived and is no longer updated by Apple.
The Personal LaserWriter SC suffers from the same problem as the LaserWriter IISC and the ImageWriter LQ: when printing outline, bold and shadow text in 18 point or larger type sizes, some parts of the characters may be omitted and/or garbled. The problem usually occurs when 4X fonts are used. Installing more system RAM and/or allocating more memory to the application will have no effect on the problem.

In March of 1991, this problem is fixed by using TrueType-compatible printer drivers. Apple introduced the TrueType font scaling software which is bundled with both the StyleWriter and the Personal LaserWriter LS printers. The TrueType compatible drivers are available on a Macintosh Printing Tools disk which contains the drivers for the following printers:

Printer	Version
LaserWriter	6.1
ImageWriter	6.1
AppleTalk ImageWriter	6.1
Personal LaserWriter SC	6.1
Personal LaserWriter LS	1.0
ImageWriter LQ ImageWriter	6.1
ImageWriter LQ AppleTalk ImageWriter	6.1
StyleWriter	1.0

In May of 1991 another solution was made avaliable with the release of System 7. System 7 includes a new Printing disk and Tidbit disk which contain printer drivers for the following:

Printer	Version
LaserWriter	7.0
Personal LaserWriter SC	7.0
ImageWriter	7.0
AppleTalk ImageWriter	7.0
LQ ImageWriter	7.0
LQ AppleTalk ImageWriter	7.0

Macintosh LC: Connecting to VGA Monitors

Does the Macintosh LC support VGA monitors? What are the pinouts for connecting a VGA monitor to a Macintosh LC?

This article has been archived and is no longer updated by Apple.
The Macintosh LC supports some VGA monitors. However, there are many different modes/types of VGA timing. The following specifications show the VGA timing characteristics supported by the Macintosh LC.

Dot clock = 25.175 MHz
Dot = 39.722 nsec
Full line = 31.778 usec
Line rate = 31.469 kHz
Full frame = 16.68 msec
Frame rate = 59.94 Hz

Here are the pinouts for connecting a VGA monitor to a Macintosh LC:

Macintosh LC VGA Connector
DB-15
---------- ----------

2 ---------- Red Video ---------- 1
1 ---------- Red Ground ---------- 6
9 ---------- Blue Video ---------- 3
13 ---------- Blue Ground ---------- 8
5 ---------- Green Video ---------- 2
6 ---------- Green Ground ---------- 7
15 ---------- Hsync ---------- 13
12 ---------- Vsync ---------- 14
14 ---------- Sync Ground ---------- 10
10 ----------|
7 ----------| Connect 7 and 10 so the sense pin ID will equal VGA

A few issues to keep in mind:

* VGA monitors may vary depending on the vendor. Check with the vendor about Macintosh LC compatibility before buying.

* Vendors have different image quality specifications. There may significant differences between Apple monitors and VGA monitors. Do a side-by-side comparison of a VGA monitor with an Apple monitor before buying.

* Third party cable vendors should have cables available for purchase soon.

* When a VGA monitor is connected as described in the pinout above, the resolution is 640 x 480. The bit-depth supported depends on the amount of VRAM installed. For example, if the Macintosh LC 256K VRAM SIMM is installed, 4-bit color (16 colors) is supported. If the Macintosh LC 512K VRAM SIMM is installed, 8-bit (256 colors) is supported.

System 7: Hardware and Memory Requirements

What hardware do I need to run System 7?
This article has been archived and is no longer updated by Apple.
System 7.0 runs on all Macintosh computers with 2MB of RAM and a hard drive. If you have a Macintosh with a 68030 microprocessor (or a 68020 with a PMMU), you can also take advantage of virtual memory (VM).

On a 2MB Macintosh running System 7.0, you have enough RAM (750K to 1024K) to run one moderate-size application like a word processor or spreadsheet.

With a 2MB Macintosh SE running System 7:

* You always have access to the desktop
* You can use most of the features of System 7
* You have about the same amount of memory for applications as you did under System 6 with 1MB of RAM.

Further, a System 7 Macintosh is as fast as a System 6 Macintosh SE, and even faster in many important operations like copying files.

Note: Turning file sharing on reduces memory available for applications by about 200K. Using on-board video on a Macintosh IIsi and Macintosh IIci can consume over 300K of memory when the monitor is set to 8-bit color.

How you use your Macintosh computer affects how much memory you will need. This makes it difficult to make a memory recommendation for a particular user.

Taking advantage of other specific features of System 7 may require other hardware like a network, color monitor, and so on.

Intrinsic units that use GLOBAL variables, either public (defined in interface) or private (defined in implementation), MUST have a data segment in addition to the code segment.

Under some circumstances, the compiler may fail to give an error message if the data segment is omitted; in that event, the system will crash when the unit is used.

System 7: Upgrade Kits and Other Sources

Must I buy a System 7 upgrade kit or can a dealer copy the disks for me?
This article has been archived and is no longer updated by Apple.
System 7 offers so many new features and capabilities that many users will want to have the System 7 User's Guides and the information offered in the System 7 Upgrade Kits. These kits include Macintosh System Software 7, reference manuals, and many extra features.

However, as in the past, some dealers may make new versions of System Software available to customers by duplicating the software onto the customer's disks.

System Software 7 is also available through users groups, electronic bulletin boards & individuals.

System 7: AppleShare 1.1 Workstation Software Is Compatible

Can I log on to a System 7 Macintosh with file sharing on from a Macintosh with AppleShare 1.1 Workstation software?

This article has been archived and is no longer updated by Apple.

Yes. AppleShare 1.1 drivers (still required on the Macintosh 512Ke) can connect to a folder shared by a System 7 user running Macintosh File Sharing.

System 7: File Sharing on a Large Network

How do I manage file sharing on a large network?
This article has been archived and is no longer updated by Apple.
File sharing is managed by each Macintosh user who has enabled it. Management involves all users naming their Macintosh computers with the Sharing Setup control panel, creating users and groups with which to share (if desired), and controlling access to the shared folders. The individual file sharing user performs these tasks.

It's a good idea for each network administrator to give each user guidelines regarding naming conventions and setting appropriate access privileges for sharing information.

System 7: Decides Among Bitmap, TrueType, and ATM Fonts

This document provides information about how System 7.x decides which font to use when different types of the same font family are installed.
This article has been archived and is no longer updated by Apple.
For this discussion:

* Bitmap Times 24.
* TrueType Times (in any size).
* An Adobe Type Manager (ATM) Times (in any size).

Screen Fonts

When you choose a font and size, the system uses the following order to decide among the possibilities for displaying type on the screen:

1) The bitmap font.
2) The TrueType font.
3) An Adobe Type Manager (ATM) font if available.
4) A bitmap font of a different size, to be scaled to the specified size.

This sequence means that the document you created in bitmap Times 24 will show up in the same bitmap font on the screen to ensure against reformatting. The system looks for the bitmap font first, and if it isn't available, it scales the TrueType font to the proper size.

PostScript Printer Fonts

When you print your document, the preference order changes. For type on a PostScript printer (such as a LaserWriter Plus, LaserWriter IINT, IINTX, IIf, IIg, LaserWriter Pro, Personal LaserWriter NT, NTR, LaserWriter Select 310, and many third-party PostScript laser printers), the order is:

1) The printer's ROM
2) The printer's RAM
3) The printer's hard disk
4) Type 1 or Type 3 PostScript files in the System Folder (stored inside the Extensions folder in System 7.0 and inside the Fonts folder in System 7.1 or later)
5) TrueType
6) Bitmap

Detailed Information on How a PostScript Printer Determines Font Type

When a job is being processed and when a font is called for in the job, the font is selected using the arbitration schemed described above, and the bitmap is built and cached in the printer's VM (RAM).

If the same font is called again later in the job, then this font in RAM is used unless it was purged by the interpreter to free up room for some other activity, such as to make room to build another font called for in the job. When the job is completed, the VM is flushed. The next job then goes through the same font arbitration process described above, until the bitmap is built in the printers VM. As long as the font is resident in VM it is used during the course of that job.

Fonts downloaded by a utility or by some other means having the same name as a font in ROM will not be used. To download a font for print jobs to call and use, it must have a unique name. There are some third-party font applications which allow you to change the name of the font. Simply renaming the font in the Mac OS does NOT change the font name. All Apple PostScript printers and most third-party PostScript laser printers manage font arbitration similarly.

Non-PostScript Printer and Fax Fonts

For printing to a non-PostScript device (such as an ImageWriter, LaserWriter IISC, Personal LaserWriter SC or LS, LaserWriter Select 300, Personal LaserWriter 300, StyleWriter, StyleWriter II, the DeskWriter by Hewlett-Packard, fax modems, and so on) the order is:

1) TrueType
2) ATM (if available)
3) A bitmap font of a different size, scaled to the specified size

Adobe Type Manager (ATM) is a utility that generates bitmap fonts for any size and resolution from Type 1 PostScript fonts. Since TrueType fonts are not PostScript, Adobe Type Manager cannot manipulate them. ATM and TrueType can work side-by-side in your system. If you have some PostScript fonts to display and print using ATM, and you have different fonts in the TrueType format, you should have no problems.

However, keeping the same fonts installed in both ATM and TrueType formats is not recommended. Because of the order of precedence (TrueType over ATM on screen and on non-PostScript printers), if you have the same font installed in both formats, the system uses TrueType -- not ATM.

System 7 Installed Fonts

The System 7 Installer automatically installs TrueType versions of Times, Helvetica, Courier, Symbol, Monaco, Geneva, and Chicago. If you need to use an ATM version of these fonts, you must remove the TrueType version from the System file (in System 7.0 or earlier) or from within the Fonts folder in the System Folder (in System 7.1 or later).

System 7: How to Prepare for It

What should I do to prepare for System 7?
This article has been archived and is no longer updated by Apple.
Apple recommends that you do the following things to prepare for System 7:

1) "Before You Install System 7" is in the Personal Upgrade Kit and the Group Upgrade kit. This stack describes features of System 7 and answers questions about upgrading.

Use the System 7 "Compatibility Checker" (a HyperCard stack), which scans your hard disk, checking the compatibility of your third-party applications, Control Panels (cdevs), and system extensions (INITs) against a database of compatibility information provided by the developers of the software. For the most up-to-date information, call the individual vendors of the software applications you use.

2) Upgrade to compatible versions of your application software.

3) Make sure you have enough RAM in your Macintosh (2MB is the absolute minimum; 4MB is strongly recommended) and that you have enough free space on your hard drive (at least 5MB).

4) If you use EtherTalk, upgrade your routers and EtherTalk drivers to Phase II.

For more information on the Compatibility Checker, search for "Compatibility Checker".

LaserWriter: Loose Screws Cause Printing to Stop

This article has been archived and is no longer updated by Apple.

Near the microswitches inside the LaserWriter, there is a bracket held in place by two screws (but no lock washers). As old toner cartridges are removed and new ones installed, these screws and the bracket become loose. This causes the toner cartridge to 'disappear to the LaserWriter' as the drive train tightens to pull the paper through, causing the LaserWriter to stop printing.

When printing stops, the tension in the drive train slackens and the toner cartridge 're-appears'. This series of events results in what appears to be a paper jam. At first, this can happen about once a week. Then it begins to happen every day. Eventually, the bracket becomes so loose that the cartridge 'disappears' entirely.

To fix the problem, just adjust the bracket and tighten the screws.

System 7: About Compatibility Checker

What is the Compatibility Checker?
This article has been archived and is no longer updated by Apple.
The System 7 Compatibility Checker is a HyperCard stack that scans your hard disk, or any other startup disk, checking the compatibility of third-party:

* Applications
* Startup documents (INITs), known in System 7 as system extensions
* Control Panel documents (cdevs)
* Chooser selectable devices (rdevs)

All compatibility information used by the Compatibility Checker came from the developers of the products. You should use the Compatibility Checker before upgrading to System 7; you can use it afterward as well. Before
using it, however, be sure to check the version and date of the Compatibility Checker itself. If it is out of date, the report it gives you will not contain accurate information about the third-party software on your disk. For instance, if you have just purchased a new version of a spreadsheet application, Compatibility Checker will be unaware of this
version and will report it as incompatible. For the most recent possible information, it is best to contact the vendors of your software directly.

System 7: Upgrade Strategy for Groups

What is the recommended System 7 upgrade strategy for groups of Macintosh computers?
This article has been archived and is no longer updated by Apple.
Apple's recommended upgrade strategy for groups of Macintosh computers is contained in the System 7 Group Upgrade Guide. This guide is an integral part of the System 7 Group Upgrade Kit. The kit contains all the tools and
necessary information on how to plan, implement, and manage a group transition to System 7. This kit contains System 7 software and other software on disks and on a CD-ROM.

Network administrators and users who support a group of Macintosh computers should buy the System 7 Group Upgrade Kit (Order #M8221LL/A):

System 7: Moving Documents from System 6 to System 7

Can I move documents from my System 6 Macintosh to a Macintosh running System 7? Will my documents change?
This article has been archived and is no longer updated by Apple.
You can move documents between a Macintosh running System 6 and a Macintosh running System 7 without any problems. In most cases, your documents will not change their appearance. For example, if your document uses Times font in size 12, your document won't change.

An exception occurs when you have TrueType fonts installed and you have documents using numerous odd type sizes. Line endings for such documents may change slightly when you open the document under System 7. Also, the document's formatting may be slightly different. You may need to readjust your document's formatting to have the format for lines and paragraphs appear exactly as before. This happens because the substituted TrueType fonts are more accurate and true to the printed output you'll get. But if you want the document to look exactly like it did under System 6, just remove the TrueType fonts from your System file. They are the ones with the triple "A" in the icon which display three different sizes when you double-click on them.

Pascal: Reading DOS 3.3 Diskettes

This article has been archived and is no longer updated by Apple.

Both Pascal and DOS 3.3 use the same recording format on the diskettes. Pascal can read a DOS diskette with the UNITREAD procedure, but there is a hitch: Pascal uses 512 byte blocks, while DOS uses 256 byte sectors. The following table shows the correspondence between Pascal's block number and DOS's track and sector numbers. Columns 4 and 5 refer to bytes 0..255 of the block and columns 2 and 3 refer to bytes 256..511.

(1) BLOCK	(2) TRACK	(3) SECTOR	(4) TRACK	(5) SECTOR
6	1	0	1	E
7	1	D	1	C
8	1	B	1	A
9	1	9	1	8
10	1	7	1	6
11	1	5	1	4
12	1	3	1	2
13	1	1	1	F
14	2	0	2	E

The rest of the disk is arranged the same, except that the track number increases.

System 7: How to Quit from an Application That Hangs

Under System 7, how do I force a hung application to quit?
This article has been archived and is no longer updated by Apple.
Built into System 7 is the ability to force an application to terminate. To do this, simultaneously press the Command, Option, and Escape keys. This feature should be used with extreme caution. You should definitely not rely on this as a usual way to quit an application.

It is particularly useful in the event that you have unsaved work in other applications when your current application hangs. By using this "force quit" feature, you can return to the Finder and save the work in your other applications. But because of possible corrupted memory after force quitting an application, you should restart your computer after using this feature.

TrueType: How to Use with System 6 (8/94)

Can I use TrueType with System 6?

This article has been archived and is no longer updated by Apple.
The TrueType Disk Set (INIT plus fonts and drivers) is no longer available. However there are some additional sources for the TrueType Init needed for System 6. The TrueType init comes with the following printer software:

* LaserWriter Select 300 - TrueType Init is on Disk 2 Printer Software.
* Personal LaserWriter 300 - TrueType Init is compressed. Use Installer.
* Personal LaserWriter 320 - TrueType Init is compressed. Use Installer.
* StyleWriter - TrueType Init is on StyleWriter Installation Disk 1.
* StyleWriter II - TrueType Init is on Disk 2 Printer Software.

If you know someone who has the TrueType Disk set disks, you can also install them to get TrueType functionality with a System 6 machine.

Your Macintosh must have at least 1 MB of RAM and system software version 6.0.7 or later. Although the TrueType software works on System 6.0.5, Apple hasn't thoroughly tested it under 6.0.5. Therefore, we recommend you upgrade to System 6.0.7 or later. System 7.0 users don't need to install this software because the TrueType functionality is built into System 7.

The TrueType INIT goes into the root level of the System Folder. The fonts need to be installed using the Font/DA mover found on Disk 1 (version 4.1)

Full installation instructions can be found in the ReadMe file on Disk 1.

The TrueType Disk Set includes:

System 7: How to Use ATM instead of TrueType

Can I turn off TrueType when using System 7 and ATM (Adobe Type Manager)?
This article has been archived and is no longer updated by Apple.
TrueType is part of the Macintosh System Software. If you prefer to use ATM fonts, remove the TrueType fonts from the System file.

System 7: Virtual Memory and Ejectable Media

Can I use virtual memory on ejectable media such as a Zip drive, Jaz drive, Syquest drive or a Bernoulli box? Can I use them at all with virtual memory?

This article has been archived and is no longer updated by Apple.

You can use removable media storage devices such as those mentioned above when virtual memory is turned on, but they cannot be the volume on which the virtual memory swap file is stored. The operating system will not let you select a removable media for the storage of your virtual memory swap file. (For this reason, removable media are grayed-out in the Memory control panel.)

If you use a removable hard disk and a normal hard disk, choose the normal hard disk for the Virtual Memory swap file. If the only hard disk attached to your Macintosh is a removable one, you cannot use System 7's Virtual Memory feature.

System 7: Memory Needed for a Macintosh IIsi

How much memory do I need with System 7 and a Macintosh IIsi?

This article has been archived and is no longer updated by Apple.

If you want to run System 7 on a Macintosh IIsi and are using its built-in video capabilities, Apple recommends that you have more than 2MB of RAM. System 7 works with 2MB of RAM, but with limited space for running your application software.

System 7: No Need for the 32-Bit QuickDraw INIT

Do I need the 32-bit QuickDraw INIT with System 7?

This article has been archived and is no longer updated by Apple.

No. 32-Bit QuickDraw has been integrated into System 7, and the INIT is no longer needed to get the benefits of 32-Bit QuickDraw. The System 7 Installer will delete the old 32-Bit QuickDraw INIT from your System Folder during installation.

System 7: Preparing an Apple Hard Drive for Virtual Memory

Why do I get a message that says my hard drive needs to be updated when I try to turn on Virtual Memory (VM)?
This article has been archived and is no longer updated by Apple.
If you have not initialized your hard drive with a System 7 compatible version of the hard drive formatting software, you may need to do so before the system allows you to activate virtual memory.

If you have a third-party (non-Apple) hard drive, you may need to obtain from the manufacturer an updated version of the correct formatting software for that drive. If you have an Apple hard drive, you can update your hard drive software using the instructions below. The process does not affect the data on your hard drive, and it is very simple.

1) Locate the System 7 disk marked "Disk Tools".
2) Restart your computer with the "Disk Tools" floppy.
3) Launch the application HD SC Setup.
4) Click the "Update" button.
5) Click Quit.

If you are moving from System 6.0.x to ANY version of Sytem 7.x, you can follow these steps.

Pascal: Error Messages

This article has been archived and is no longer updated by Apple.

--> "ERROR: WRITING OUT THE FILE. PRESS <SPACEBAR> TO CONTINUE."

This message can be generated in one of three ways:

1. File names are restricted to 10 characters, not including the volume name prefix or the .TEXT suffix; a name longer than that will generate the error immediately without accessing the disk drive.

2. The error will be generated if there is insufficient room on the root disk to save the new file. This condition is particularly prone to occur when Pascal is updating the workfile, since Pascal always saves the new copy of the file before removing the previous copy.

3. The directory is limited to 77 entries. If you try to save a 78th, the error will be generated, even if there is enough room on the disk for the file.

--> "NO ROOM ON VOLUME" or "CODE WRITE ERROR"

These messages may be displayed if there isn't enough room to write the file to the specified volume. This error can occur in the Filer, Compiler, Assembler, or Linker, and can usually be corrected either by using the Filer "Krunch" option (to consolidate unused blocks) or by removing unnecessary files.

--> More on "CODE WRITE ERROR"

During creation of a code file on the boot disk, the Assembler creates a temporary file called LINKER.INFO on the boot disk; this file stores linkage information that is later written into the final block of the code file. If the code file is directed to the boot disk during the assembly, the largest unused block of disk space is opened for the code file. If the disk has been Krunched recently, there may be no space available for opening LINKER.INFO, in which case the "CODE WRITE ERROR" message will be displayed. To rectify the problem, simply "Make" an 8-block file on the boot disk, and then Make a 1-block file. (The names of these files are unimportant). After that, R)emove the 8-block file, thereby separating the space into two distinct areas and creating a place for LINKER.INFO to live. NOTE: This error may also occur in the Compiler, since the Compiler also creates a LINKER.INFO (though only during very large compiles when the system needs to temporarily swap out information). The fix is the same.

If an error occurs when you use the include file option, "Make" a 4-block file on the volume where the compiler resides, and name it SYSTEM.SWAPDISK. Doing so makes it possible for the Compiler to swap out some information in order to read in the new directory in preparation for the include file.

The Pascal (version 1.0) compiler error #407 ("Too Many Libraries") can usually be avoided by changing the length of the text file being compiled. The problem is corrected in Pascal version 1.1.

System 7: System 6 Fonts Still Used

What will happen to fonts in my old System file when I install System 7?
This article has been archived and is no longer updated by Apple.
You keep all of your existing fonts. While TrueType installs a number of TrueType fonts with System 7, TrueType fonts complement any bitmap fonts available on your Macintosh.

Remember these points:

* All of the fonts in your System 6 System file are retained in System 7.
* If you request a font size that is available as a bitmap, your Macintosh uses the bitmap.
* If you use a size for which you do not a have a bitmap, your Macintosh scales the appropriate TrueType outline.
* If you remove a bitmap from your System file, the Macintosh uses the TrueType font. Depending on the font and size you request, you will end up with either a bitmap font OR a TrueType font. Regardless of whether it's a bitmap or a TrueType font, your text will look great.

System 7: Suitcase and Master Juggler

Under System 6, I've used Suitcase and Master Juggler, so my fonts don't take up space in my System file. Do I need these products with System 7?

This article has been archived and is no longer updated by Apple.

Before System 7, Macintosh System software limited the number of fonts you could have in the System file. With System 7, that limit is so much greater that you can, for all practical purposes, disregard it. You may still want to use programs like Suitcase and Master Juggler to organize sets of fonts that you don't need access to all the time. Keep in mind also that one TrueType file, which can produce all point sizes in that font, takes up much less space in your system than the files for the equivalent bitmap fonts.

System 7: Italic, Bold, and Bold Italic in TrueType

Why are Italic, Bold, and Bold Italic listed as separate typefaces for TrueType (and Postscript fonts), but not for bitmap fonts?
This article has been archived and is no longer updated by Apple.
When you're using a bitmap font and you choose Italic or Bold from the Style menu, the italic or bold type you see on the screen is a manipulation of the plain bitmap typeface. The plain font itself is ?modified--slanted forward for italic or thickened ?for bold--to create the style you've chosen.

TrueType and PostScript fonts give you separate, specially-designed typefaces, not just manipulations of the plain typeface, for italic, bold, and bold-italic styles. These look even better than the modified bitmaps, and are truer to the original designs.

System 7: A/UX 2.1 Not Compatible

Article Change History

09/02/92 - UPDATED
* To include information on A/UX 3.0.

Is A/UX software compatible with System 7?

This article has been archived and is no longer updated by Apple.
A/UX 3.0 is compatible with System 7.

A/UX version 2.1 is not compatible with System 7. The A/UX 2.1 startup application cannot be launched from a System 7 system. System 7 can't run in a Macintosh partition under A/UX 2.1.

Users who require A/UX functionality and who want to run System 7 should upgrade to version 3.0 of A/UX.

A/UX systems are network-compatible with System 7 systems. Users of the Macintosh partition under A/UX and still running System 6 should upgrade their LaserWriter drivers to version 7.0. This will make them printer-compatible with System 7 computers on the network.

System 7: Upgrade Information for AppleCD SC

Is the Apple CD-ROM system extension compatible with System 7.0?

This article has been archived and is no longer updated by Apple.
Versions of the Apple CD-ROM system extension prior to 3.0 are incompatible with System 7. Version 3.0 is mostly compatible with System 7, but version 3.1 is recommended. Users should install the Apple CD-ROM software BEFORE installing System 7.

The upgrade to version 3.1 is free, and the files can be found in the Upgrade folder on the System 7 Information bulletin board (use BB Pathfinder to locate this bulletin board), as well as on the System 7 Group Upgrade Kit CD.

The AppleCD SC hardware is compatible with all Macintosh systems that have a SCSI interface.

System 7: Upgrade Information for Apple Hard Disks

Is System 7 compatible with all Apple hard disks formatted with HD SC Setup?

This article has been archived and is no longer updated by Apple.
Some hard disks that have been formatted with older versions of HD SC Setup may require an updated driver in order to function with Virtual Memory. IT IS NOT NECESSARY TO REFORMAT THE DRIVE. If the Memory control panel indicates the drive needs updating, follow the instructions in the System 7 Personal Upgrade Kit to use HD SC Setup to update the driver.

All Apple internal and external hard disks are compatible with all Macintosh systems that have a SCSI interface.

The version of Apple HD SC Setup that ships with all hard disks is compatible with System 7, but version 2.0.4 is the recommended version.

The upgrade to version 2.0.4 is free, and the files can be found in the Upgrade folder on the System 7 Information bulletin board, as well as on the System 7 Group Upgrade Kit CD.

Reducing Objective C Message Overhead

This article discusses ways to reduce Objective C performance overhead.

This article has been archived and is no longer updated by Apple.

Q: My Objective-C messages take too long compared with C function calls. What can I do?

A: We have chosen to pay a certain performance cost in exchange for the benefits of object-oriented programming. What is really important is to amortize the added overhead of a message send over the cost of running your program. The cost of writing and maintaining correct code is also a consideration.

There is a way to optimize tight loops in code. The **methodForSelector:** method returns a pointer to the actual C function used to implement a method. This can be used at the beginning of a tight loop to cache the call. For example:

```
IMP func;

func = [anObject methodForSelector:aSelector];
while (loopingTightly) {
   ...
   func(anObject, @selector(aSelector), args ...);
   ...
}
```

As long as does not change its value in the inner loop, this technique does not sacrifice any of the advantages of Objective-C (e.g., dynamic binding) and is just as efficient as normal C. Be careful when using this method with methods which pass C types as arguments or expect them as return values; because of the lack of a prototype, non-object variables may be handled incorrectly. See the NSObject class documentation for a full discussion of this problem and its workaround.

System 7: Upgrade Information for Apple Scanner

Is the Apple Scanner software compatible with System 7.0?
This article has been archived and is no longer updated by Apple.
Version 1.0 of the AppleScan application and the Scanner system extension are mostly compatible with System 7. Version 1.0.2 of AppleScan and version 1.0.1 of Scanner are the recommended versions. Users should upgrade to these versions after installing System 7.

Upgrades to these versions are free, and the software is posted to Apple Software Updates on the Apple Support Web site.

System 7: Upgrade Information for AppleShare File Server

Is the AppleShare File Server software compatible with System 7?

This article has been archived and is no longer updated by Apple.
No. The AppleShare File Server software version 2.0 is not compatible with System 7 and should not be installed on a System 7-based Macintosh system.

AppleShare is fully network-compatible with both System 6 and System 7. Both System 6 and System 7-based Macintosh users can access an AppleShare File Server running on a System 6-based machine.

AppleShare Server 3.0, which was announced on October 15, 1991, is fully compatible with System 7. For upgrade information, please locate the article titled "AppleShare Server 3.0: Upgrade Information".

System 7: Upgrade Information for Inter■Poll

Article Change History

05/27/93 - REVIEWED

Is Inter*Poll compatible with System 7?

This article has been archived and is no longer updated by Apple.
Yes. Inter*Poll version 1.0 is mostly compatible with System 7, and version 1.0.1 is fully compatible. The update to Inter*Poll is free and the software is posted on AppleLink. Users should upgrade the Inter*Poll software after installing System 7. Inter*Poll will work with both System 7 and System 6 systems over the network.

Inter*Poll will work with both System 7 and System 6 systems over the network. The Responder functionality is now built into System 7, and installing System 7 removes the Responder extension from a System 6 system. If a System 6.0.x Mac is upgraded with System 7 printers drivers, the network administrator using Inter*poll (Apples network administrator software) will get a blank line for that system's LaserWriter driver version number. There is no problem viewing System 7 drivers on System 7.0 Macs. The Sys 6 responder can't read the System 7 driver resources.

Q: How can I make the Workspace Tools Inspector recognize my application as one of the default tools for TIFF files? Currently, when selecting a TIFF file in Workspace, the default tools are Workspace, Icon, Scene, and Edit.

A: You must perform the following steps:

In Release 2:

· Use the Inspector Panel in InterfaceBuilder to modify the **Project Attributes** of your application.

· Select **Doc1.** Enter **tiff** as the Document Extension. If you want to specify an icon for your tiff document, you can specify one by using the SET button (see ../Developer_Environment/adding_app_and_file_icons.rtf for more details).

· Save your project, and recompile.

In Release 3:
· Launch ProjectBuilder and select the Attributes button.

· Select tiff from the System File Types list and the corresponding icon appears in the Document Icons and Extensions well. If you want to specify an icon for your tiff document, you can drag a tiff image of your icon into the well. Change the label below the icon to be the desired extension.

· Save your project, and recompile.

All Releases:
· To verify that you have completed the proper steps, you can view the file test.iconheader, assuming that your application's name is test. It should list one line for your application icon, and one line for your tiff document icon, if you have specified one.

Example:

```
F test test app
S tiff test tiff
```

· Make sure that your application resides in the Workspace default search path, which is

```
~/Apps:/LocalApps:/NextApps:/NextDeveloper/Apps:/NextAdmin:\\
/NextDeveloper/Demos
```

For example, you can add it to your Apps directory (~/Apps).

· In the Workspace, choose Update Viewers from the View menu (or type Command-u) to update the File Viewer. Open the Workspace Tools Inspector. When you inspect a TIFF file with the Tools inspector, you should see the test app as an additional default tool. You can specify your test app as the default tool now by selecting it and clicking OK.

Q: Why don't the buttons in my Webster.app appear?

Q: In Release 1, when I invoke Webster through the Define command in the Request menu, Webster starts up, and my word is entered in the text field, and yet nothing displays in the definitions window. Furthermore, the buttons aren't there. Why?

Q: In Release 2 and later, when I invoke Webster through the Define command in the Services menu, Webster displays the Alert panel

"Ancillary material does not exist (~/Library/References/Dictionary//tiff)

and

"Dictionary files do not exist in ~/Library/References/Webster-Dictionary/."

And if I wait, the application displays a panel

"Error providing service Define in Webster".

Webster starts up, and my word is entered in the text field, and yet nothing shows up in the definitions window. Furthermore, the buttons aren't there. Why?

A: You probably have a directory called /LocalLibrary/References or ~/Library/References, without Webster-Dictionary or Webster-Thesaurus subdirectories. In Release 1, if this is the case, you can verify it by checking your console window in Workspace Manager. Look for error messages of the form

couldn't open '/LocalLibrary/References/Webster-Dictionary/source'
can't find Webster's Dictionary!

To correct the error, make two symbolic links in a Shell:

ln -s /NextLibrary/References/Webster-* /LocalLibrary/References

and restart Webster. (Substitute "~" for "/LocalLibrary" as appropriate.)

NeXTSTEP PPD Files

Postscript Printer Definition files, or PPD files, contain information about the specific features supported by a printer. An application needs this information to make use of these features. For example, for an application to be able to select the upper or lower paper tray of a printer that has two trays, it needs a PPD file for that printer describing the two-tray capability and the commands necessary to select a tray.

A number of PPD files are provided with NEXTSTEP. The default NEXTSTEP installation includes the most common files. Additional files are available on the NEXTSTEP CD-ROM. If you have a printer for which NeXT does not supply a PPD file, you may be able to get the PPD file from Adobe Systems, Inc. or from the printer vendor. You can then install the file and use it with NEXTSTEP. NEXTSTEP can use PPD files in Macintosh and DOS formats (DOS format is easier to install).

If a printer does not appear in PrintManager, the PPD file for the printer has not been installed. There are three places to look for PPD files:

- First, install the additional PPD files from the NEXTSTEP CD-ROM. See "Installing PPD Files from CD-ROM" below.

- If your printer is still not listed, see if Adobe supplies a PPD file for your printer. See "Obtaining PPD Files from Adobe" below.

- If Adobe does not have the PPD file for your printer, check with the printer manufacturer. See "Obtaining PPD Files from Printer Manufacturers" below.

If you obtain a PPD file from Adobe or the printer manufacturer, you need to install it so that NEXTSTEP can recognize the file. See "Installing PPD Files Not from NeXT" below.

This article has been archived and is no longer updated by Apple.

Where PPD Files Go

NEXTSTEP Release 3

You can put PPD files in several different locations: **/NextLibrary/PrinterTypes**, **~/Library/PrinterTypes**, **/HostLibrary/PrinterTypes**, and **/LocalLibrary/Printertypes**. Which directory you should use depends on where you got the PPD file and who needs to access the printer.

If you need to modify the PPD information for a printer, put the modifications in separate files that "include" the standard PPD information using the ***Include** directive. The NEXTSTEP 3.2 Printing release note contains full details on how to name these custom files, as does NeXTanswer #1073, "New Options in Printing." However, please note that there is an error in both of these documents. The custom files should be placed in **.../PrinterTypes/CustomPrinters**, not **.../PrinterTypes/Custom** as the release note and NeXTanswer indicate.

Installing PPD Files from CD-ROM

NEXTSTEP Release 3

Every NEXTSTEP system and upgrade comes with a CD-ROM disk containing the entire user release. This makes it easy for users with the basic software configuration to copy files from the CD-ROM onto their system from **/NextLibrary/PrinterTypes/English.lproj**.

NEXTSTEP Releases 3.0 and 3.1

To install all PPD files in these releases, install the Documentation package, located in the **/NextCD/Packages** folder on the CD-ROM.

NEXTSTEP Releases 3.2 and 3.3

PPD files in Releases 3.2 and 3.3 are located in two packages: PrinterPPDs and ImagesetterPPDs. Both of these packages are located in the **/NextCD/Packages** folder on the CD-ROM.

Obtaining PPD Files from Printer Manufacturers

Your printer manufacturer should have a current set of PPD files for all of its PostScript printers. Most printer manufacturers have disks with PPD files ready to send out on request. Call your printer manufacturer to find out about distribution methods for PPD files. In the meantime, your printer manufacturer may be able to suggest a PPD file for a comparable printer that you can use.

If your printer manufacturer offers a choice between Macintosh and DOS formats, choose the DOS format. You can use DOS files under NEXTSTEP by changing just the file name. To use Macintosh files, you need to translate them first (i.e., substitute newline characters for the carriage returns that the Macintosh uses at the end of lines. You can use public domain utilities to perform this translation, or use the UNIX command **tr**).

Obtaining PPD Files from Adobe

Receiving PPD Files via FTP from Adobe Systems' FTP Server

If a PPD file is publicly available from Adobe Systems, you can get it through Adobe's FTP server.

For anonymous FTP access, use the following information:

hostname: ftp.adobe.com (130.248.1.8)
username: anonymous
password: any (use your e-mail address)

PPD files are located in **/pub/adobe/PPDfiles/DOS**. The directory also contains a text file, **FILENAME.MAP**, which lists the available PPD files and their corresponding file names. If your printer is not listed in **FILENAME.MAP** then Adobe Systems does not currently provide a PPD file for your printer; contact your printer manufacturer to obtain a PPD file.

Installing non-NeXT PPD Files

NEXTSTEP Release 3

If your printer manufacturer offers a choice between Macintosh and DOS format, choose the DOS format. You can use DOS files under NEXTSTEP by changing just the file name. To use Macintosh files, you need to translate them first (i.e., substitute newline characters for the carriage returns that the Macintosh uses at the end of lines. You can use public domain utilities to perform this translation, or use the UNIX command **tr**).

NEXTSTEP works only with PPD files that have proper names. PPD files sent out on DOS floppy disks are not usually named properly for NEXTSTEP. You can get the proper name by examining the PPD file itself.

1 Copy the DOS file onto a NEXTSTEP file system before you change its name.

2 In the header information of the PPD file, look for an entry something like this:

*ModelName: "AGFA AccuSet"

3 Make the name of your NEXTSTEP PPD file the same as the model name, replacing spaces with underscores (_) and slashes (/) with percent symbols (%). Then, append the extension **.ppd** to the file name. For example, the above model name would translate to the file name **AGFA_AccuSet.ppd**.

4 Copy the appropriately named file into one of the **...Library/PrinterTypes** folders, and you should be up and running with your new printer type. (You may have to quit and restart PrintManager to get it to recognize the new PPD files.)

System 7: Upgrade for MacDFT & the Coax/Twinax Card

Are the Coax/Twinax card and MacDFT compatible with System 7?
This article has been archived and is no longer updated by Apple.
The Apple Coax/Twinax card is compatible with System 7, and the installer for System 7 updates the A/ROSE software needed to run that card. The Coax/Twinax card can be used with System 7 and compatible third-party products.

MacDFT is not compatible with System 7. Users who require MacDFT functionality should not upgrade to System 7 until the upgrade to MacDFT is available.

System 7.x: Upgrade Information for MacTCP

Is MacTCP compatible with System 7 and higher?
This article has been archived and is no longer updated by Apple.
MacTCP is compatible with System 7. The specifics follow:

* For System 7.0 and System 7.0.1, use MacTCP version 1.1 or higher.

* For System 7.1 and System 7 Pro (7.1.1), use MacTCP version 1.1.1 or higher.

* For System 7.1.2 and System 7.5, use MacTCP version 2.0.4 or higher.

Note: As of this article, the current version of MacTCP is version 2.0.6.

The applications: "MacTCP 2.0.4 to 2.0.6 Patch" and "MacTCP Admin 2.0.6 Patch" are ResCompare resource patching applications. Applying the appropriate patch to a COPY OF YOUR ORIGINAL ("clean") MacTCP or MacTCP Admin control panel will upgrade your copy to version 2.0.6.

All licensed copies of MacTCP 2.0.4 can be upgraded. For users of earlier 2.x versions (2.0 and 2.0.2) must first be updated to version 2.0.4 before updating to version 2.0.6.

Pascal II: Compiler Options

The Pascal compiler swapping option (*$S+*) should be used if the compile fails due to lack of symbol table space. This option should be the first line of the text, preceding the program statement. Swapping MUST be used in compiling units. Please see page 68 of the Apple Pascal Language Reference Manual for more details.
This article has been archived and is no longer updated by Apple.
The Pascal compiler list option (*$L+*) should not be used with Pascal version 1.0, since this will result in the loss of the code file and possibly of the directory. Instead, direct the list to the printer (*$L Printer:*), the console (*$L Console:*), or to a named file ON ANOTHER VOLUME: for example, (*$L Mydisk:Myfile.text*). We recommend using the printer. NOTE: This problem has been corrected in Pascal 1.1, and will work as described in the Pascal reference manuals.

The (*$U-*) "lex level" compiler option will result in a non-executable codefile and so should not be used for compiling user programs. This option is intended for working on the system level; it requires files and information not available to the user.

Compiler options in Pascal version 1.0 must be in capitals. In version 1.1, capitals and lower case are interchangeable.

System 7: Upgrade Information for Apple Tape Backup 40SC

Is the Apple Tape Backup 40SC software compatible with System 7?

This article has been archived and is no longer updated by Apple.
No. The Apple Tape Backup 40SC software and Tape Disk system extension are not compatible with System 7, and no update is planned. Apple recommends the use of third-party backup software for use with the Apple Tape Backup 40SC. (The Apple Tape Backup 40SC hardware is fully compatible with all Macintosh models running System 7.)

Take the following steps to recover system information from tapes generated with the Apple Tape Backup 40SC:

1) Use a System 6-based Macintosh to recover the files.

2) Use the File Sharing capability of System 7 to transfer the files to the System 7 system.

In the case of a complete hard disk recovery, follow these steps:

1) Install System 6 on the hard disk.

2) Use Tape Backup 40SC to recover the information.

3) Reinstall System 7.

System 7: Compatibility with Macintosh Software Utilities

This article describes how System 7 works with some commonly-used Macintosh software.
This article has been archived and is no longer updated by Apple.
The following software is no longer needed because its functionality has been incorporated into System 7:

- 800K Eject INIT
- Font/DA Mover
- Memory Manager INIT
- TrueType INIT

The following software will not work with System 7 and no update is planned. Users of this software should purchase third-party equivalents.

- HD Backup
- MacroMaker

The following software is incompatible with System 7, but compatible versions are included with the System 7 Personal Upgrade Kit:

- Apple File Exchange (prior to 7.0)
- Disk First Aid (prior to 1.5)
- LaserWriter Font Utility (prior to 6.0; this program has been supplanted by LaserWriter Utility)
- TeachText (prior to 7.0)

The following software is incompatible with System 7. Compatible versions are supplied with the System 7 Group Upgrade Kit, and are also posted in the Upgrade folder on the System 7 Information bulletin board:

- QuickMount (prior to 1.0.7)
- Apple CD-ROM (prior to 3.0)
- The Namer (prior to 2.1; the functionality of this program has been supplanted by LaserWriter Utility)

Data Type Storage Sizes for Mach

This article discusses the sizes of the fundamental C data types under the Mach operating system.
This article has been archived and is no longer updated by Apple.
Q: How many bytes of storage do the various fundamental data types require under OPENSTEP for Mach? What are the maximum and minimum values for the various arithmetic data types?

A:

TYPE	SIZE	MINIMUM	MAXIMUM
char	1 byte = 8 bits	-128	127
unsigned char	1 byte = 8 bits	0	255
short	2 bytes = 16 bits	-32768	32767
unsigned short	2 bytes = 16 bits	0	65535
int	4 bytes = 32 bits	-2147483648	2147483647
long	4 bytes = 32 bits	-2147483648	2147483647
unsigned int	4 bytes = 32 bits	0	4294967295
unsigned long	4 bytes = 32 bits	0	4294967295
float	4 bytes = 32 bits	1.17549435e-38f	3.40282347e+38f
double	8 bytes = 64 bits	2.225073858507201e-308	1.797693134862316e+308

- The **unsigned** and **signed** keywords don't change the size of the type they qualify.
- Pointers occupy 4 bytes.
- The **void** type occupies no space.

If you happen to forget any of the sizes, you can quickly remind yourself by running gdb and typing:

```
print sizeof(type)
```

The minimum and maximum values are defined as constants in **<limits.h>** and **<float.h>**.

The NeXTSTEP mach implementation used the same values.

NeXTSTEP 3.0: Fatal Signal 11 Error

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Q: I'm getting the following error message from the C++ compiler:

cc++: Internal compiler error. Program collect got fatal signal 11.

What's going on?

A: You have encountered a known bug in the C++ compiler. The bug has been fixed in Release 3.1. This is a bug in the program **collect** that relates to the use of alloca. Essentially, the program **collect** runs out of stack when "collecting" your application, causing it to crash.

There is a workaround. Just increase the stacksize in the shell. Use the **limit** command to increase your stacksize. Like this:

% limit stacksize 10000

In Release 1 this workaround always works. However, in Release 2 this workaround does not work when used with the **make** utility. **make** hardwires the stacksize rather than reading it from the users default. So, in Release 2 or later (unless you have 3.1 or later, in which this bug is fixed) you must link by hand, or write a little shell script to do it for you.

System 7: Specifications

This article contains some specifications of Macintosh System 7.
This article has been archived and is no longer updated by Apple.

Built-in Fonts

Two types of fonts are supplied with System 7: TrueType and bitmapped.
TrueType fonts include:
* Times (plain, bold, italic, and bold italic)
* Helvetica (plain and bold)
* Symbol
* Courier (plain and bold)
* Chicago
* New York
* Monaco
* Geneva

Print Drivers

The following print drivers are included with System 7
* ImageWriter and AppleTalk ImageWriter
* LaserWriter
* Personal LaserWriter LS
* Personal LaserWriter SC
* ImageWriter LQ and AppleTalk ImageWriter LQ
* StyleWriter

Networking Capabilities

With System 7, the AppleTalk network system supports LocalTalk, Ethernet (EtherTalk), or Token Ring (TokenTalk). Over 16 million nodes per network are provided for with AppleTalk Phase II networking. Using Macintosh file sharing, up to 10 folders per machine can be shared, each having an unlimited number of enclosed folders. Up to 10 guest users can be connected to a networked hard disk, with up to 50 guest users identified in the Users and Groups file. User management is built into the software to allow entry of user names, passwords, group memberships, and access privileges for opening and modifying files.

Memory and Storage

With 24-bit addressing, up to 8MB of physical memory can be accessed and up to 14MB of memory can be accessed with virtual memory, depending on which model Macintosh is being used. With 32-bit addressing, 1 gigabyte of physical memory is accessible (without taking into account the hardware limitations) and up to 1 gigabyte of virtual memory is accessible.

A minimum of 2MB of RAM is required to run System Software Version 7.0. The amount of memory used by System 7 alone (without any additional third party software) is 1MB to 1.25MB, depending on configuration.

Approximately 2.5MB to 4MB of disk space is consumed by System 7, depending on configuration.

Compatibility

System 7 is compatible with most Macintosh System 6 applications. The processor is compatible with 68000, 68020, and 68030 microprocessors, 68851 Paged Memory Management Unit (PMMU), and 68881 and 68882 floating-point units (FPUs).

Disk Formats

The following disk formats are supported by System 7: 400K, 800K, 1.4MB Macintosh disks, 720K and 1.44MB read/write MS-DOS or OS/2.

Files and Volumes

Up to 31 characters with mixed case, spaces, and symbols are allowed with System 7's file naming conventions.

Maximum file and volume size is 2 gigabytes. The maximum number of files per volume is 65,536.

The maximum number of volumes open at once as well as the maximum number of tasks supported are limited only by the amount of available system memory.

Sound
Sound can be played from disk and input to disk. The maximum number of simultaneous sound channels is 4.

HyperCard: How to Control Which Version Gets Launched

I have HyperCard 2.0 and HyperCard 1.2.5 on the same AppleShare server. When I double-click on a HyperCard stack, sometimes I want HyperCard 2.0 to launch, sometimes I want HyperCard 1.2.5 to launch.

How can I control which version of HyperCard is launched?
This article has been archived and is no longer updated by Apple.
On your personal computer, if two applications differ only in their version numbers, then the last copy installed is the one that gets launched. However, this rule doesn't apply to applications on an AppleShare volume.

A sure way to eliminate the version (or last-installed) confusion is to change the Creator of the applications you don't want to launch.

For example, use ResEdit to change the Creator of HyperCard from "WILD" to "FRED". When you double-click on a stack, the system looks for the application whose creator matches the creator of the document or stack. If you have another copy of HyperCard (say, 2.0v2) on a mounted device, it will be launched. Saving files from the changed application is unaffected (they still have "WILD" for their creator).

Change the creator of all non-current HyperCard applications to something other than "WILD" (try "DLIW"; it's probably not used by other applications). All stacks launched will come up in HyperCard 2.0v2. To open the stacks in other versions, launch the desired application and use "Open╔" in the file menu.

NeXTSTEP Hard Drive Recovery Tips

Disclaimer

This document pertains to the NeXTSTEP operating system (versions 3.2 and previous). Apple Computer no longer provides support for these products. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software.
This article has been archived and is no longer updated by Apple.

Procedure

Steps 1 and 2 depend on the type of computer running NEXTSTEP. After that it's the same for all NEXTSTEP machines.

If you have an Intel based Computer:

1. Put your installation floppy in the floppy drive, the installation CD-ROM in the CD-ROM drive and turn on your computer.

2. At the boot: prompt, type:

If your internal hard drive is IDE

fd()mach_kernel -s rootdev=sd0a

If your internal hard drive is SCSI

fd()mach_kernel -s rootdev=sd1a

3.2 will ask for installation language and boot drivers; answer the questions and don't fear, this will not re-install NEXTSTEP.

If you have a NeXT Computer:

1. Put your installation floppy in the floppy drive, the installation CD-ROM in the CD-ROM drive and turn on your computer.

2. When the machine displays "testing system" press

*Command-Command-tilde*_on_numeric_keypad

You should get the "NeXT ROM Monitor".

At the NeXT> prompt, type:

bfd -s

For all types of computers:

The system will start in "single user mode". When it is finished, you will see a # prompt.

2a. ***If you are running NS3.2 for Intel*****, load the floppy driver:**

/usr/etc/driverLoader D=Floppy

3. You need to mount your internal hard drive on the filesystem. Here's the command:

if you have an IDE disk

```
mount -n -o ro /dev/hd0a /disk
```

if you have a SCSI disk

```
mount -n -o ro /dev/sd0a /disk
```

Your entire hard drive is now /disk.

4. Put a blank floppy disk into the floppy drive and format it with this command:

```
/usr/etc/disk -i /dev/rfd0b
```

5. Mount the floppy disk on the filesystem, as the directory /floppy

```
mount -n /dev/fd0a /floppy
```

6. Change directories, for example:

```
cd /disk/pat/files
```

7. List the files in a directory:

```
ls
```

8. Copy a file onto the floppy disk:

```
cp logo.ps /floppy
```

9. The floppy will fill up eventually. When that happens, you need to unmount it. Here's how:

```
umount /floppy
```

10. Remove that floppy from the floppy drive and build another floppy, starting with step 4.

Tips:

If you have files with spaces or ampersands in the names, for example:

```
Dan Resume.ps
```

you must copy them this way:

```
cp "Dan Resume.ps" /floppy
```

If you get the error "*command not found*" you need to use the full path for commands:

```
mount: /usr/etc/mount
umount: /usr/etc/umount
ls: /bin/ls
cp: /bin/cp
```

If you get the error "*/private/etc/mtab00026: read only file system*" when umount'ing a floppy, you need to type

```
sync; sync; reboot
```

and start this procedure again, using another blank floppy. The data you wrote to the first floppy got copied. You do not need to copy it again.

You can check the sizes of files with the *-l* option to *ls*.

ls -l

System 6.0.7: Installing Comm Toolbox

I want to install MacTerminal 3.0 on a Macintosh LC. Unfortunately, MacTerminal 3.0 has to have certain Comm Toolbox resources into the System file. This means I have to restart from the original Installer disk, which happens to be System 6.0.5, a System that doesn't work on Macintosh LC.

I've tried to upgrade the installer disk to System 6.0.7. When I start the Macintosh LC and try to execute the installer script, the computer asks for the "Communications 1" disk. All I can find is a disk called "Communications", not "Communications 1".

This article has been archived and is no longer updated by Apple.
The Communications Toolbox installation diskette that ships with MacTerminal is named "Communications". An essentially identical diskette shipped with the Macintosh Communications Toolbox package is named "Communications 1."

The Communications Toolbox 1.0 Installer Script on both diskettes (and the 6.0.7 Network Product Installer) asks you to insert the diskette "Communications 1", but you may use either diskette. Updating the CTB Installation diskette to version 6.0.7 has no effect on the resources and their locations called for by the installation script.

There isn't enough room on the CTB installation disk to conveniently update it to System 6.0.7 using the script "minimal software for any Macintosh". Many people choose to install minimal software for a specific Macintosh. An alternative is to not update the CTB installation diskette to System 6.0.7 but instead start the Macintosh with another diskette containing System Software 6.0.7. Then insert the CTB installation diskette and run the installer.

Another possibility is to get the 6.0.7 Network Products Installer off AppleLink. Use the BB Pathfinder and search on "Software and 6.0.7".

Booting NeXTSTEP From an Alternate Hard Disk

When an Intel computer is powered on, it looks for a device to load software from. The process of finding this software and loading it is known as "booting."

The computer looks for a bootable disk in the floppy drive, the IDE drive, and any attached SCSI drives from lowest to highest SCSI ID, in that order. The computer starts up from the first bootable device it finds. (Note that it is generally possible to disable the IDE drive, in which case the computer will not try to boot from it, using the BIOS configuration of your machine. On some machines it may also be possible to make the BIOS check for fixed disks before looking for a floppy.)

In certain circumstances, you might want to install NEXTSTEP on a SCSI drive, while using the IDE drive for DOS or other operating systems. Or you might want to install NEXTSTEP on a SCSI disk that is not the lowest SCSI ID in the chain. Or perhaps you wish to install NEXTSTEP on the second of two IDE drives. In these cases, additional configuration of your computer needs to be done after installation in order to make it bootable.

This NeXTanswer explains how to configure your system so you can boot NEXTSTEP from a hard disk drive other than the first one encountered during the boot process. The basic procedure consists of creating a small (7 megabyte) NEXTSTEP partition on the primary hard disk drive and then creating some configuration files on this partition which tell NEXTSTEP where to find the necessary boot files. The procedure for booting to the non-primary hard disk drive from the NEXTSTEP boot floppy is also detailed.

This article has been archived and is no longer updated by Apple.

Warning

This is an unsupported configuration. NeXT Technical support will not provide any assistance in configuring your system this way.

Configuration Issues

During installation, it is necessary to have the IDE drive disabled if you wish to install to a SCSI drive. If you have multiple SCSI drives, you must install NEXTSTEP on the drive that is currently configured as device 0. (Note that SCSI device numbers are not the same as SCSI ID numbers. For futher information see NeXTanswer 1109_SCSI_Setup.) Once you have successfully installed NEXTSTEP, boot into NEXTSTEP.

If you are planning on leaving the SCSI drive that NEXTSTEP is installed on configured as device 0, there is no additional configuration that needs to be done; proceed to "Booting from Floppy" below. If however you wish to change the device number of the NEXTSTEP SCSI disk, you must make a change to the **fstab** file.

Open a shell, and create a backup copy of the **fstab** file.

localhost> **su**
localhost# **cp /etc/fstab /etc/fstab.orig**

Next, using your favorite editor edit the **fstab** entry such that it reads as follows:

```
#
# DO NOT DELETE THIS FILE, IT IS REQUIRED FOR BOOTING
#
# This file contains information used to mount local hard disks.
# Consult your Network and System Administration manual
# for information on adding local disks. Information on the format
# of entries in this file can also be found in the fstab man page.
#
/dev/sd***n***a / 4.3 rw,noquota,noauto 0 1
```

The only change you need to make is to change the ***n*** to the device number of your NEXTSTEP SCSI drive. Again, note that SCSI device numbers are not the same as SCSI ID numbers; see NeXTanswer 1109_SCSI_Setup, for further information.

For an IDE drive, the entry should be:

/dev/hd1a / 4.3 rw,noquota,noauto 0 1

Please note the "hd" in this entry. This is what distinguishes a SCSI drive from an IDE drive at the system device level.

Now shutdown your system and reconfigure your hardware so the NEXTSTEP SCSI disk will be assigned the device number you entered above. (If you made a mistake and are unable to configure your hardware properly, you will need to reinstall NEXTSTEP or find a way to boot from another device, so be very careful! If you do need to boot from another device, see NeXTanswer 1468_Upgrading_from_3.1_to_3.2_bug)

Booting from Floppy

One way to boot to NEXTSTEP when it is not installed on the primary hard drive is to first boot from floppy. To do this proceed as follows:

Insert the NEXTSTEP CD-ROM Installation disk in drive A and boot the system.

After some messages the machine will pause while displaying the boot: prompt. Having determined the device number of your SCSI drive (0 if it is the only drive), type the following where ***n*** is the device number:

boot: **sd(*n*)mach_kernel**

Note that there are no spaces in the above command.

Your system will boot from the SCSI hard drive.

A second IDE drive can be booted with the following command:

boot: **hd(1)mach_kernel**

Booting from Hard Disk Drive

While booting from floppy is effective, it is somewhat annoying. One solution is to create a small NEXTSTEP partition on the primary hard disk (i.e. the disk that gets booted from by default). Because of a bug in the **disk** command, this partition must be at least 7 megabytes in size. Creating such a partition and configuring it properly allows you to automatically boot into NEXTSTEP without having to enter the sd(n)mach_kernel command. To do so, follow these steps:

Boot NEXTSTEP following the instructions for booting from floppy, above.

Log in as root. (If necessary, set a password for the me account and log out first.)

Start up Terminal.app (located in **/NextApps**) and use the NEXTSTEP fdisk to create a NEXTSTEP partition on the primary hard disk. You must be root to do this.

For an IDE disk type:

localhost# **/usr/etc/fdisk /dev/rhd0h**

For a SCSI disk type:

localhost# **/usr/etc/fdisk /dev/rsd0h**

(For all further instructions, replace hd with sd if you are using a SCSI disk instead of an IDE disk.)

This command puts you in interactive mode; from there create a 7 megabyte NEXTSTEP partition. Save the changes to disk. (Note all of the normal caveats of using fdisk: old information stored on your hard disk drive will be erased, so make sure to back up your files before doing this!)

Use the disk utility to create a NEXTSTEP filesystem on that partition:

localhost# **/usr/etc/disk -i /dev/rhd0a**

This command also creates the necessary NEXTSTEP boot blocks on the drive. See the UNIX manual page for the **disk** command for more information.

Next mount the newly created NEXTSTEP partition:

localhost# **/usr/etc/mount /dev/hd0a /disk**

Copy the minimal system configuration information from the NEXTSTEP filesystem:

localhost# **cd /**
localhost# **tar cf - usr/Devices/System.config | (cd /disk ; tar xf -)**

Finally, edit the system config info file
/disk/usr/Devices/System.config/Instance0.table
replacing the line
"Kernel" = "mach_kernel";
with
"Kernel" = "**sd(*n*)**mach_kernel";

Once again, ***n*** is the device number of the SCSI drive with NEXTSTEP installed on it. If you have installed NEXTSTEP onto a second IDE drive, the entry should read:

"Kernel" = "**hd(1)**mach_kernel";

When you reboot your system, it should give you the "n for NEXTSTEP, d for DOS" prompt; typing n makes the machine boot from the SCSI drive with NEXTSTEP installed.

After you're up and running

After you get your system booted, you may want to make changes to your configuration, such as adding a video driver, or a network driver. Remember that your system always gets its configuration information off of the mini-partition when it boots, but any configuration changes you make with Configure.app reside on the complete NEXTSTEP partition. After making any changes with Configure.app, you must copy /usr/Devices/System.config back to the mini-partition, and make the same changes to it as shown above.

LaserWriter IINTX: Benefits of Attached Hard Drive

What are the benefits of using an attached hard drive with a LaserWriter IINTX?

1) Is the purpose of a hard drive to:
A. increase printing speed through RAM caching?
B. centrally locate PostScript fonts?
C. to free up space on a local hard drive?
D. all the above?

2) Currently, TrueType fonts cannot be downloaded to a hard drive connected to a LaserWriter IINTX. Will this feature be used in the future and will you gain any benefit by loading TrueType fonts onto a hard drive connected to a LaserWriter IINTX?

This article has been archived and is no longer updated by Apple.
The purpose of a hard drive is primarily to centrally locate PostScript fonts and to free up space on a local hard drive, but can be all of the above.

A hard disk attached to a LaserWriter IINTX speeds printing only if the fonts required for a document are stored on it and thus do not need to be downloaded over a network. Other uses generally slow down printing unless the hard disk speed versus the network speed is appreciably different. For example, if font scan-conversion (idle-time or otherwise) stores its cache to the hard disk, printing is slowed because it takes time to retrieve the cache from disk. An extremely fast disk may overcome this problem, but we haven't performed any tests that clearly prove this.

Choice B, centrally locating PostScript fonts, is a valid use, and can speed up printing if those fonts are used in the document in question.

Choice C, freeing up local hard disk space, is also valid because every PostScript font located on the hard disk need not be located on the user's hard disk. Therefore the fonts can be removed from the user's hard disk, freeing up storage space. Of course, a backup of these fonts should be kept somewhere in case the LaserWriter IINTX's hard disk ever fails.

Another way to improve the printing speed of a LaserWriter IINTX, or any PostScript LaserWriter for that matter, is to download fonts using the LaserWriter Font Utility. If there is adequate RAM (or disk space) available, downloading the fonts can greatly increase print speed. And fonts downloaded to RAM are faster than those downloaded to disk, so optimum performance depends on what fonts are used most often and where they are stored.

The difference between using the Font Utility to download fonts versus allowing them to be automatically downloaded with your document is that those fonts downloaded with the utility will persist until the printer is reset or powered off. Those fonts that are downloaded automatically with a document only persist for that job. The next job requiring the same fonts would download them again. This increases network traffic and job overhead appreciably, and with a busy network, can slow printing significantly.

Similar issues are involved with TrueType fonts. With current LaserWriter models, the TrueType fonts and rasterizer are not available in ROM. Therefore, all TrueType fonts used in a document must be downloaded, along with the rasterizer. These fonts and their scan converted data will only be persistent for each job, so the effect will be nearly identical to that with PostScript fonts downloaded from a user's System Folder. The LaserWriter

Font Utility, version 7.0, is able to download TrueType fonts as well as PostScript fonts.

Apple 300/1200 Baud Modem: No Eight-Bit Command

This article has been archived and is no longer updated by Apple.

The Apple 300/1200 baud modem supports data formats up to 8 bits. There is no command to change the data handling of the modem from 7 bits to 8 bits. When data is sent to the modem, as a series of level transitions, the modem simply converts those transitions to frequency shifts. It does not care what the data structure is, up to the specified limits, and will echo whatever is sent to it.

LaserWriter and WordPerfect: Correcting Timeout Problem

I'm printing a WordPerfect document from a DOS machine using a LaserWriter IINT. After the first 40 pages have printed, the document no longer prints and junk comes out on the paper. No matter where I start, the printing never goes beyond 40 good pages.

This article has been archived and is no longer updated by Apple.
After limited testing, it appears that WordPerfect takes a long time to repaginate lengthy documents during printing. This creates a time lag that can exceed AppleShare PC's timeout for printer connections and causes the job to fail. Symptoms are seen as pauses between pages that wouldn't seem to warrant any additional computation. If one of these pauses is long enough, it causes AppleShare PC to terminate its connection with the LaserWriter.

Try increasing the timeout value used in AppleShare PC's DA program at connection time. If increasing the timeout value helps but does not solve the problem, leave the timeout value blank. This can delay other users from accessing the LaserWriter, but not too badly.

Macintosh IIsi: Sound Driver Incompatibilities and CE QuickMail

I'm having problems using CE QuickMail's voicemail on a Macintosh IIsi. I can send voice messages only to other Macintosh IIsi computers. No other Macintosh computers can play my messages.

This article has been archived and is no longer updated by Apple.
The problem is that QuickMail requires a compatible sound driver on every Macintosh, but the drivers on your network may be different on each Macintosh. On a Macintosh IIsi or Macintosh LC, QuickMail uses the Apple Sound Manager in System 6.0.7. On other Macintosh models using Farallon's MacRecorder, QuickMail uses Farallon's sound driver. And while the Sound Manager understands the new AIFF format sounds, as well as the older 'snd' resource format sounds, older versions of Farallon's driver did not understand the AIFF format.

When a Macintosh IIsi records a sound (using the Sound Manager), the sound is stored internally in AIFF format. Other Macintosh IIsi users can play the sound because they're using the same sound manager. Macintosh computers using the MacRecorder and earlier versions of the Farallon sound driver can't play the message.

You can either install a Farallon sound driver on all your Macintosh IIsi systems or get an upgrade. Farallon has sold the MacRecorder hardware and software to MacroMedia (formerly MacroMind) and they're handling support for the product.

NeXTSTEP 3.1/3.2 sendmail Patch

These instructions show you how to install the **sendmail** patch on NeXT and Intel-based computers running NEXTSTEP‰ Release 3.1 or Release 3.2. The patch is distributed in an Installer package file named **SendmailPatch.pkg**.
This article has been archived and is no longer updated by Apple.
Installing Update 1 of the Sendmail Patch for NEXTSTEP Release 3.1 & 3.2

Download the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.2/SendmailPatch.compressed

Two versions of **sendmail** are provided with NEXTSTEP Release 3.1 and 3.2: **sendmail** (version 5.67) and **sendmail.old** (version 5.52). Late last year, the Computer Emergency Response Team (CERT) identified a handful of security problems with NeXT's versions of **sendmail**. These problems are described in CERT Advisories CA-93: 16 and CA-93: 16A. **SendmailPatch.pkg** contains copies of **sendmail** and **sendmail.old** that fix these security problems.

1. If you received the **SendmailPatch.pkg** file via NeXTmail‰ or another electronic source, place a copy of the file in a location where you can access it when you log in as **root**.
2. Log in as **root**.
Only the superuser, **root**, can install the package. If you're not sure how to log in as **root**, see your system administrator.
3. If you received the **SendmailPatch.pkg** file on a floppy disk, insert the disk in the floppy disk drive and choose Check for Disks from the Workspace Manager‰ application's Disk menu. When the disk icon appears in the File Viewer, double-click it to open it.
4. Double-click the **SendmailPatch.pkg** file.
5. Click the Install button in the Installer package window. When the panel asks you what kinds of computers you want to install the software for, select the kind of computer you're using and click Install. Then click Continue in the panel that warns you you're about to overwrite existing files.
6. When the installation is complete, choose Quit from the Installer menu.
7. Choose Log Out from the Workspace menu and then click the Restart button in the Login window.

Note: You must restart your computer after installing the package.
The next time you start up your computer, it will take advantage of the new versions of **sendmail**.

For more information about CERT advisories, contact CERT. Past advisories, information about FIRST representatives, and other information related to computer security are available by anonymous FTP from **info.cert.org**. You can also contact CERT at:

CERT Coordination Center
Software Engineering Institute
Carnegie Mellon University
Pittsburgh, PA 15213-3890
Internet E-mail: **cert@cert.org**
Telephone: (412) 268-7090 (24-hour hotline).
CERT personnel answer 8:30 a.m.-5:00 p.m. EST(GMT-5)/EDT(GMT-4), and are on call for emergencies during other hours.

For information about logging in and out, the Workspace Manager application, and the Installer application, see the NEXTSTEP *User's Guide*.
For more information about **sendmail**, see the *NEXTSTEP Network and System Administration* book.

ADDENDUM:

The **sendmail** patch NeXT recently made available does not update the entire **sendmail** subsystem. In the original system software release, the files **/usr/bin/mailq** and **/usr/bin/newaliases** are *hard links: to the same file (i-node) as **/usr/lib/sendmail**. The patch replaces only the file called **/usr/lib/sendmail**, and does not affect the other two links. This leaves a system with the patch installed still open to some of the vulnerabilities addressed by the patch.

(**/usr/bin/mailq** provides a summary of the messages in the message queue, and **/usr/bin/newaliases** regenerates the flat-file aliases database, which *is* referenced by **sendmail**.)

To close the vulnerabilities, follow the steps below.

1. Either log in as **root** and run the Terminal application, or, in a Terminal window, **su** to **root**.

2. Run the following commands (you type what's in **boldface**):
rhino-6# **cd /usr/bin**
rhino-7# **rm mailq newaliases**
rhino-8# **ln -s ../lib/sendmail mailq**
rhino-9# **ln -s ../lib/sendmail newaliases**

3. It is *not* necessary to reboot the computer, nor to restart the **sendmail** daemon.

The result of this procedure is to replace the old **mailq** and **newaliases** with relative symbolic links to the new **sendmail**.

This procedure should be performed on all NEXTSTEP computers on which the **sendmail** patch has been installed. Failure to complete the installation according to these instructions can result in your system remaining open to some of the vulnerabilities which the **sendmail** patch addresses.

Macintosh Monitors: Visible Raster Area Specifications

What is the visible screen size of Macintosh monitors? How much of the page width can you see? For example, on the 13-inch RGB monitor you can see from 0 to 8.5 inches.

Please tell me the visible width of the:

* Macintosh 12-inch Monochrome
* Macintosh 12-inch RGB
* Apple Two-Page Monochrome

NeXTSTEP 3.2: Partitioning Large Disks

Disclaimer

This document pertains to the NeXTSTEP operating system (versions 3.2 and previous). Apple Computer no longer provides support for these products. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software.

Question

Why am I unable to partition and initialize my new big disk? It's a 2.7 gigabyte SEAGATE ST43400N. I get errors like "boot block extends beyond front porch."

Answer

There's a bug in the 3.2 and older versions of BuildDisk and /usr/etc/disk when initializing large disks. Basically, they miscalculate the parameters for the partition label on the disk, and use the wrong values for creating file systems on the disk. If you have a large disk (greater than 2 GB), you can partition and initialize the disk using the following procedure.

1 Do a low level format to make sure the drive is in the factory default state:

```
localhost# sdform /dev/rsd1a
device = /dev/rsd1a block size = 512 capacity = 2777 MBytes

***FORMATTING THIS DISK CAUSES ALL DISK DATA TO BE LOST***
This will take approximately 92 minutes.

Do you wish to proceed? (Y/anything) Y

Disk Format in progress...
***Format Complete***
```

2 Run /usr/etc/scsimodes to obtain the actual disk parameters:

```
localhost# scsimodes /dev/rsd1a
SCSI information for /dev/rsd1a
Drive type: SEAGATE ST43400N
512 bytes per sector
99 sectors per track
21 tracks per cylinder
2737 cylinder per volume (including spare cylinders)
9 spare sectors per cylinder
21 alternate tracks per volume
5688446 usable sectors on volume
```

3 Create an entry in /etc/disktab for the disk:

```
ST43400N|ST43400N-512|SEAGATE ST43400N-512:\\
:ty=fixed_rw_scsi:nc#2737:nt#21:ns#99:ss#512:rm#3600:\\
:fp#320:bp#0:ng#0:gs#0:ga#0:ao#0:\\
:os=sdmach:z0#64:z1#192:hn=localhost:ro=a:\\
:pa#0:sa#4194304:ba#8192:fa#1024:ca#32:da#4096:ra#10:oa=time:\\
:ia:ta=4.3BSD:\\
:pb#4194304:sb#1493822:bb#8192:fb#1024:cb#32:db#4096:rb#10:ob=time:\\
:ib:tb=4.3BSD:
```

The important things to note here are where to copy the data from the scsimodes output to the disktab entry. The items bolded above (cylinders per volume, tracks per cylinder, sectors per track, and bytes per sector) are copied from the scsimodes info. See the disktab(5) man page for details.

The size of the front porch (fp#) should be 320 for disks formatted with 512 byte sectors and 160 for disks formatted with 1024 byte sectors. The location (block numbers) of first level boot code (z0#, z1#) should be 64 and 192 for disks formatted with 512 byte sectors and 32 and 96 for disks formatted with 1024 byte sectors.

The last 4 lines of the disktab entry define the partitioning of the disk. All partitions must be less than or equal to 2*1024*1024*1024 bytes in size. The pa#0 field says partition a starts at block 0. The sa# field indicates that it contains 4,194,304 blocks (512 bytes each, 2Gb total). In the next set of fields, the starting point (pb#) and size (sb#) for the b partition are defined. Note that the starting point for the b partition is the same as the starting point of the a partition plus its size (0+4194304).

If more than two partitions are required, add a line of the form:

:pc#4194304:sc#1493822:bc#8192:fc#1024:cc#32:dc#4096:rc#10:oc=time:\\
:ic:tc=4.3BSD:

Make sure that the partition start and partition size fields all add up to the appropriate numbers. The sum of the sizes for all partitions (pa#, pb#, ...) and the front porch (fp#) should be less than or equal to the usable sectors on the volume.

4 Write the label (partition info) to the disk and initialize the file systems:

localhost# disk -t ST43400N -i /dev/rsd1a
disk name: ST43400N
disk type: fixed_rw_scsi
writing disk label
Writing /usr/standalone/boot
creating new filesystem on /dev/rsd1a
/usr/etc/newfs -n -v /dev/rsd1a
/etc/mkfs /dev/rsd1a 4194303 99 21 8192 1024 32 10 90 4096 t
Warning: 4096 bytes per inode impossible due
to cylinder group size, using 15620 bytes per inode
Reduce cylinder group size to reduce bytes per inode.
Warning: 748 sector(s) in last cylinder unallocated

super-block backups (for fsck -b#) at:
16, 33672, 67328, ...
creating new filesystem on /dev/rsd1b
...
initialization complete

5 Make an entry in /etc/fstab for the new disk like the one below. If you do not, the first partition will mount automatically, but the remaining partitions will not be visible. Refer to the mntent manpage for information on writhing fstab entries.

/dev/sd1a /partition1 4.3 rw,noquota 0 1
/dev/sd1b /partition2 4.3 rw,noquota 0 1

NeXTSTEP 3.0: MAB Application Services Problems

Disclaimer

This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Q: Why don't the services from my MAB [Multiple Architecture Binary] applications show up on my Release 3.0 machine?

A: When the service description file is located in an app wrapper of a MAB application and placed in ~/Apps, the services do not get properly registered on a Release 3.0 machine. However, the services are correctly registered on a post-Release 3.0 machine. This is a MAB bug in Release 3.0.

The workaround is to place a file or directory with a ".service" extension in either ~/Library/Services or /LocalLibrary/Services. A file with a ".service" extension must be a valid service description file. A ".service" directory must contain a valid service description file named "services" (e.g., the service description file would be named something like ~/Library/Services/myOwn.service or /LocalLibrary/Services/ALocalOne.service/services). Note that the extension "**.service**" does not end in an "s", but the file named **services** does. Also, the Workspace Manager only registers the services in these directories when the user logs in, it doesn't automatically update the service cache during a working session.

For more information on installing services, refer to ../AppKit/installing_new_services.

NeXTSTEP DO Connection Problems

Q: I have a client application which is connecting to a server on another machine. When I specify the hostname, the client successfully connects to the server. The problem occurs when I specify the "*" wild card as the hostname parameter to **connectToName: onHost:fromZone:**. In this instance the connection fails and nil is returned. What might cause this?

A: When you explicitly specify the hostname, the Distributed Object (DO) request is efficiently routed using the usual TCP/IP routing mechanism to make the connection. However, when you use a wild card search for the host, each machine on the subnet must be queried. For this reason the wild card search limits itself to the immediate subnet. In other words, the wild card search fails if the two machines are not on the same subnet; the two nmserver processes are unable to find each other.

Also see the documentation for **+connectToName:onHost:fromZone:**.

There are two possible strategies you can employ to avoid using the wild card when you don't know the hostname:

1) Hard code a machine name. Of course, it would be a friendly gesture to allow this machine name to be changed in the Preferences panel of the Client application.

2) Register the name with NetInfo. For example, you might want to create a new directory in the **locations** directory called **myAppNameServer**. The **myAppNameServer** directory would contain a property which lists the value of the hostname where the server is located.

A/UX: How To Turn On IP Forwarding (8/94)

I just discovered that A/UX defaults IP forwarding to OFF. This means that an A/UX system with more than one interface no longer "knows" how to route IP traffic regardless of how in.routed is configured.

This article has been archived and is no longer updated by Apple.
To enable forwarding, run adb on the kernel. Log in and type the following command:

```
# adb -w -k /unix /dev/kmem

a.out file = /unix (COFF format)
core file = /dev/kmem
ready

ipforwarding?D

ipforwarding: 0

ipforwarding?W 1

ipforwarding: 0x0 = 0x1

$w
$q
#
```

This changes the "ipforwarding" constant in the kernel. Reboot, and when
the system comes back up, IP forwarding will be on.

For more details on IP forwarding refer to the A/UX Network System Administration manual section on "Configuring and Managing a TCP/IP Network".

NeXTSTEP 3.2 DBKit Oracle Adaptor Patch Overview

This is a MAB version of the Oracle Adaptor based on the Pre-Release 3.3 version of the Oracle Adaptor. It contains the following bug fix :

· The default Oracle date format in Release 3.2 does not return time. It hardcodes TO_CHAR(columnName, 'MM/DD/YYYY') when it extracts a date/time.
(Bug Ref#40437, Ref#38749)

This patch should only be applied to systems using DBKit with NeXTSTEP 3.2.
This article has been archived and is no longer updated by Apple.
Download the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.2/3.2_OracleAdaptor.compressed

With this patched adaptor, you can use a dwrite to change the default date format which is currently specified as "MM/DD/YYYY".

In a terminal shell, specify the following dwrite:

localhost> dwrite MyApp OracleAdaptorDateFormat "DD Year Month HH:MI:SS"

Note: You can specify any valid SQL format string. You can have a different format string for each application. Note that the dwrite only applies to a single machine and to a particular application. You would have to specify the dwrite on each machine individually.

· If the dwrite solution is not generic enough, you can change your application code to include the following methods:

```
@interface DBDatabase (DateFormatStringExtensions)

- (const char *)dateFormat;
// This returns the current date format string used by the
// adaptor. It will never return NULL.

- (const char *)defaultDateFormat;
// By default this returns "MM/DD/YYYY". This default date
// format can be overridden by a dwrite:
// % dwrite <AppName> OracleAdaptorDateFormat "<format string>"
// This method never returns NULL.

- setDateFormat:(const char *)newDateFormat;
// This method is used to set the date format used by the
// adaptor. It will override the built-in and dwrite
// defaults. If newDateFormat is NULL, the default date
// format will be used. This method returns self.

@end
```

In your application code, you can set the format inside appDidInit: for instance, by sending to the DBDatabase instance variable the method setDateFormat. For example:

```
- appDidInit:sender
{
[[module database] setDelegate:self];

fprintf(stderr, "current date format %s\\n",
[[module database] dateFormat]);
[[module database] setDateFormat:"DDth Month/YYYY"];

return self;
}
```

Usage
Hardlink to this patched oracle adaptor by adding the following option to your Makefile.preamble
OTHER_OFILES = /MyDirectory/OracleAdaptor.adaptor/OracleAdaptor

Known Problems not fixed in this Oracle Adaptor Patch

Bug Reference **39247**

Identical names in joined tables generate ambiguous queries that fail.
The Oracle server will generate the following error message:
ORA-00918 Column Ambiguously defined.

Workaround: Use different names.

Bug Reference **41992**

Update of date fields alone will fail.

NeXTSTEP 3.2 /etc/restore patch

These instructions show you how to install update 1 of the **/etc/restore** patch on a NeXT or Intel-based computer running NEXTSTEP‰ Release 3.2. The patch is distributed in an Installer package file named **RestorePatch.pkg**.

This article has been archived and is no longer updated by Apple.

Installing Update 1 of the /etc/restore Patch for NEXTSTEP Release 3.2

Download the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.2/RestorePatch.compressed

This patch fixes a problem with the Release 3.2 version of **/etc/restore** where set user and group id bits are not retained on restored files. A symptom of missing set user and group id bits after restoring a NEXTSTEP system disk is the inability to log in as a user other than **root**.

1. If you received the **RestorePatch.pkg** file via NeXTmail‰ or another electronic source, place a copy of the file in a location where you can access it when you log in as **root**.
2. Log in as **root**.
Only the superuser, **root**, can install the package. If you're not sure how to log in as **root**, see your system administrator.
3. If you received the **RestorePatch.pkg** file on a floppy disk, insert the disk in the floppy disk drive. (If you have an Intel-based computer, choose Check for Disks from the Workspace Manager‰ application's Disk menu.) When the disk icon appears in the File Viewer, double-click it to open it.
4. Double-click the **RestorePatch.pkg** file.
5. Click the Install button in the Installer package window. When the panel asks you what kinds of computers you want to install the software for, select the kind of computer you're using and click Install. Then click Continue in the panel that warns you you're about to overwrite existing files.
6. When the installation is complete, choose Quit from the Installer menu.
The new **/etc/restore** is now available to restore **/etc/dump** backups.

For information about logging in and out, the Workspace Manager application, and the Installer application, see the NEXTSTEP *User's Guide*. For information about **/etc/restore**, see *NEXTSTEP Network and System Administration* and the UNIX manual pages for **dump** and **restore**.

Apple CD-ROM Explorer Disk: Using with Macintosh IIsi

I have a Macintosh IIsi with the 12-inch RGB display and an AppleCD SC. The problem is my CD-ROM Explorer disk included with my AppleCD SC was designed for a 13-inch RGB monitor. Also, the HyperCard stacks on the CD-ROM Explorer are incompatible with HyperCard 2.0, the version required when using 6.0.7 system software.

My questions are:

1) Is Apple going to revise the CD-ROM Explorer disk?

2) If yes, what is the upgrade policy and how do I get a copy?

This article has been archived and is no longer updated by Apple.
The CD-ROM Explorer HyperCard stacks are compatible with HyperCard 1.2.5 and HyperCard 2.0 under Macintosh System Software 6.0.7.

As of July 1992, the CD-ROM Explorer disk is no longer included with Apple CD-ROM drives.

Apple Sound Chip: Macintosh IIfx Audio Output Level (4/95)

I am trying to match up line levels for my audio system and I need to know the audio output level of the Macintosh IIfx. This information is not in the Macintosh IIfx manual.

This article has been archived and is no longer updated by Apple.

The following information is from the "Guide to the Macintosh Family Hardware" available through Addison-Wesley dealers. This information applies to all models using the Apple Sound Chip.

"The external sound jack is at standard line level (approximately 1.5 volts peak-to-peak) and its source impedance is approximately 47 ohms. The jack is capable of driving a headphone load of 8 to 600 ohms, or the input to almost any audio amplifier or amplified speakers. It will not adequately drive a directly connected external speaker. The external sound jack is short-circuit protected."

NeXTSTEP 3.2: DOS File System Patch

This update corrects a number of problems in the way NEXTSTEP Release 3.2 works with DOS file systems, most notably:
· You can now use DOS partitions larger than 32 megabytes, without risk of corrupting the files on that partition.
· The File Viewer now accurately reports the space available on DOS partitions larger than 32 megabytes.
· You can now use removable DOS hard disks (such as Syquest and Bernoulli disks).
· You can now work with some of the DOS partitions that NEXTSTEP Release 3.2 was unable to "mount."

Caution: Take care not to fill up all the space on a DOS partition, or NEXTSTEP will stop running. (The File Viewer reports the space available on a DOS partition when you select the partition or any file or folder in it.)

Only the superuser, **root**, can install the package. If you're not sure how to log in as **root**, see your system administrator.
3. If you received the **DOSFileSysPatch.pkg** file on a floppy disk, insert the disk in the floppy disk drive and choose Check for Disks from the Workspace Manager‰ application's Disk menu. When the disk icon appears in the File Viewer, double-click it to open it.
4. Double-click the **DOSFileSysPatch.pkg** file.
5. Click the Install button in the Installer package window. When the panel asks you what kinds of computers you want to install the software for, select your kind of computer and click Install. Then click Continue in the panel that warns you you're about to overwrite existing files.
6. When the installation is complete, choose Quit from the Installer menu.
7. Choose Log Out from the Workspace menu and then click the Restart button in the Login window.

Note: You must restart your computer after installing the package.
The next time you start up your computer, it will take advantage of the new DOS file system software.

HyperCard 2.0: How To Get Updates

There are several commercial stacks shipping that require HyperCard 2.0 v1, HyperCard 2.0 v2, and so on. I want to use these stacks but don't want to necessarily buy a full HyperCard bundle from Claris. Is there a way for me to get an update from Apple, or must I purchase HyperCard from Claris to get an update?

This article has been archived and is no longer updated by Apple.
HyperCard is a Claris product, and customers should contact them regarding software updates. Claris will send a disk containing HyperCard 2.0v2, HyperCard Fonts, and a small Home stack to any owner who requests it.

Customers who purchased the Software Update package for HyperCard or the Network Admin package will be shipped the same software Apple is including with its computers.

Claris says that the HyperCard 2.0 upgrade is the best way to go. The upgrade includes the new Script Language Guide, a guide to the new features, and the complete set of HyperCard disks.

HyperCard 2.0: "Command-Option-S" Key Problem

In HyperCard 2.0, the Command-Option-S key combination brings up a dialog box requesting the location of the System folder, rather than the stack script as expected.

This article has been archived and is no longer updated by Apple.

Command-Option-S opens the script of the stack in use. This did not change in HyperCard 2.0. You might have a macro set up to do something different. In QuicKeys 2, Command-Option-S is set up as the start/stop sequence for macro recording. Make sure that nothing like this is in use and the problem should be eliminated.

HyperCard 2.0: Version Numbers Explained (2/95)

How do I know if I have the latest released version of HyperCard 2.0? Is there a way to get that information other than using the "Get Info" command?

This article has been archived and is no longer updated by Apple.
The latest released version of HyperCard is 2.2. This is the version returned by the Get Info command. The "version" property of HyperCard returns version information on the HyperCard application and stacks. On pages 645 to 647 of, "HyperTalk 2.0: The Book", by Dan Winkler and Scot Kamins, is an excellent description of the property and the information it returns. However, Claris Corporation uses a different numbering scheme for release versions of its software.

Running HyperCard 2.2, type "put the long version". The string "02218000" appears in the message box.

* The first two digits (02) show major revision number.
* The next digit (2) is for minor revisions.
* The fourth digit (1) is for bug fix revisions.
* The next two digits (80) show the development stage. In this case, the 80 means it is released software.
* The final digits (00) are only applicable on unreleased software.

Translating all of this using the Apple scheme results in 2.2.1. Claris uses only the major and minor revision number in its releases. The bug fix revision number translates to a "v" number with 0 being equivalent to "v1", 1 to "v2", and so on.

NeXTSTEP 3.2 libMallocDebug Patch

The malloc debug library shipped with NEXTSTEP Release 3.2 inadvertently was compiled with a setting that nullifies the checking for damaged memory regions. This version of libMallocDebug has no changes, other than being compiled with the flag on, so it reinstates the checking. This library is a multi-architecture binary, both Intel and Motorola are supported. You can use lipo(1) to thin the library if desired. This software is not supported by Apple Computer.

NeXTSTEP 3.2: Large IDE Drive Problems

Disclaimer

This document pertains to the NeXTSTEP operating system (versions 3.2 and previous). Apple Computer no longer provides support for these products. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software.

Overview

The NEXTSTEP 3.2 IDE driver uses your computer's BIOS to retrieve IDE drive geometry. Because of this, there is a problem that may occur when installing NEXTSTEP 3.2 on drives larger than 504Mb.

Problem

Your motherboard's BIOS may report translated IDE drive geometry that confuses the NEXTSTEP 3.2 IDE driver and causes a kernel panic. Most BIOSes will fake the actual geometry for disks that exceed the imposed limitations by performing a translation. As an example, if the disk is actually 2048 cylinders, 16 heads, and 63 sectors per track, the BIOS may translate this to 1024 cylinders, 32 heads, and 63 sectors per track.

The geometry limitation of 1024 cylinders, 16 heads, and 63 sectors per track stems from a combination of both the ATA specification and your BIOS's limits. The IDE limitations are set in the original ATA specification (see http://www.symbios.com/ftp/pub/standards/io/ata/ata-r4c.txt) . BIOS limits come from the INT 13 read/write calls that combine a 10 bit cylinder value with a 6 bit sector value into a 16 bit register. The following table demonstrates how each contributes to the limitation.

	BIOS	IDE	Limitation
Maximum Cylinders	1024	65536	1024
Maximum Heads	255	16	16
Maximum Sectors/Track	63	255	63
Maximum Capacity	7.84GB	127.5GB	504MB

If your drive exceeds this limit and the BIOS performs a translation, you may see messages similar to the following during the first phase of installation:

kernel panic
/private/tmp/mnta: bad dir in0 18435 at offset 0: mangled entry
mode = 077430, inum = 18437, fs = /private/tmp/mnta
panic: (cpu0) ialloc: dupalloc
panic: next mach 3.2: <date>; root(rcbuilder): mk-149.30.15.obj~ 2/rc_i386/release_I386
kernel panic exception (6,3,1)
waiting for remote debugger connection

Solution

Most drives have flexible configurations and permit of a range of cylinders, heads, and sectors from the system setup utility. You will have to modify these parameters so that they do not exceed the limits imposed by the BIOS and those outlined in the ATA specification. The resulting maximum capacity of the drive's geometry should not exceed any one of the following parameters:

1024 cylinders x 16 heads x 63 sectors/track x 512 bytes/sector
Yielding a maximum of 528 482 304 bytes (504Mb)

Other drives will have jumper switches which must be set to break the drive into two separate drives, effectively creating a primary and secondary disk from a single IDE drive.

If your large drive does not allow for this configuration, it may be unable to be used with NEXTSTEP. This case is rare, and you should contact the supplier or manufacturer of the drive for assistance.

Caution

In addition to the standard IDE driver, NEXTSTEP 3.3 includes a revised IDE driver that resolves the geometry problem. This updated driver asks the disk for its geometry instead of obtaining it from the BIOS. If you are currently using the NEXTSTEP 3.2 IDE driver and will be upgrading to NEXTSTEP 3.3 (or later), you may use the revised IDE driver but you will have to both reset the BIOS settings and reinitialize the drive (reinstall all operating systems). However, you may continue to use the standard IDE driver with no difference in operation.

LocalTalk PC Card: Where To Get Interface Specifications

I want to develop a server program on a PC. To do this, I suppose I'll need to get the hardware and software interface specifications for the LocalTalk PC card. Where can I get them?

This article has been archived and is no longer updated by Apple.
You may not need to get down to the hardware level. You may be better off basing your software on an existing model, such as the Open Data-Link Interface (ODI) specification. This way, you wouldn't have to adjust for each type of network card, but could work with a single model. Also, you'll save much development time by using ODI-compliant drivers already in use for many network cards. Your software could then coexist with other software that uses ODI protocol stacks--AppleShare PC, for example.

Since an ODI-based driver already exists for the LocalTalk PC Card, you could concentrate on developing your server software and basing it on the available AppleTalk protocol stack. If you want to implement a different protocol stack for the LocalTalk PC card, this also can be done within the framework of ODI, and it would still take advantage of the existing driver.

The best source of information on programming to the ODI specification is the Open Data-Link Interface Developer's Guide, available from APDA. Here is the introduction to Chapter 1:

"The Open Data-Link Interface is a new system jointly developed by Apple Computer, Inc., and Novell, Inc., that provides unmatched flexibility for both network developers and end users. The Open Data-Link Interface (ODI) includes the Multiple Link Interface (MLI) and the Multiple Protocol Interface (MPI). The MLI and MPI are the interfaces for network card drivers and protocol stacks to the Link Support Layer (LSL). The LSL provides packet transfer between these interfaces in a way that allows different protocol stacks to use link-level drivers interchangeably and simultaneously. The ODI puts an end to the need for one-driver to one-stack communication."

The entire publication includes the Developer's Guide, some sample driver notes, and a disk with code and test programs. It is available from APDA as part number M0355LL/A.

NeXTSTEP for PA-RISC Hardware Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.

HP-UX and NEXTSTEP

Q: Can I install HP-UX and NEXTSTEP onto separate partitions of the same hard disk?

A: HP-UX and NEXTSTEP use incompatible partitioning schemes and cannot be installed on the same disk. The only way to set up a dual-boot machine is by using separate hard disks for HP-UX and NEXTSTEP.

Q: Okay, I've set up a dual-boot machine using one disk for NEXTSTEP and another for HP-UX. Whenever I log in under NEXTSTEP, I get a panel which says "This disk is damaged: initialize?" with options to initialize, repair, or ignore. The default option is "Initialize." What should I do?

A: Under NEXTSTEP 3.2, this happens because NEXTSTEP attempts to mount the HP-UX disk but does not know how to read its filesystem. You should click "Ignore." *Choosing either of the other options may result in irreparable data loss on the HP-UX disk.*

This has been fixed in NEXTSTEP 3.3, you are able to add an entry in /etc/fstab that will force NEXTSTEP to ignore the HP-UX disk automatically. The disk type for the HP-UX disk should be 'ignore'. See the mntent(5) UNIX manual page for more information.

CD-ROM Compatibility

Q: What CD-ROM drives can be used to install NEXTSTEP?

A: Due to restrictions in the HP ROMs, only certain HP and Toshiba CD-ROM drives can be used to install NEXTSTEP. The recommended CD-ROM drive is the HP A2655A. The HP A1999A can be used with 7x5 systems but is incompatible with 712 systems.

The HP A2655A uses the same mechanism as the Toshiba XM-3401TA, while the HP A1999A uses the same mechanism as the Toshiba XM-3301TA. These drives may be used instead of the equivalent HP drives, but NeXT recommends contacting HP to be sure your firmware revision is compatible.

Q: Can a wider range of CD-ROM drives be used to read CD-ROMs once NEXTSTEP has been installed?

A: Yes.

Hard Drive Compatibility

Q: I've encountered some suspicious problems such as errors during installation, SCSI timeouts, and a wait of several minutes to log in to the Workspace. What's going on?

A: NeXT has discovered SCSI incompatibilities with one specific hard drive model, the Quantum LPS1080S with firmware revision 111B. The following tables summarize our findings to date.

Compatible:
Vendor Model Capacity FW rev. Verification status
HP C2247 1.0GB 0BQ3 NeXT-tested

Seagate ST3600N 0.5GB 9686 customer report
Seagate ST3600N 0.5GB 4686 customer report

* subject to limitations affecting hard drives of 2GB or greater<see below

NeXT has received conflicting information about the compatibility of the Seagate ST3600N. If you are encountering problems with the Quantum LPS1080S, please contact your HP Sales Representative for a replacement drive. In addition, if you have any additional information related to these tables, please contact NeXT Technical Support by the means listed in the Introduction.

Q: I couldn't install on my hard drive which is two gigabytes or larger. Why not?

A: There was a bug in NEXTSTEP Release3.2 in which the UNIX File System imposes a 2GB limit for disk partitions, the UNIX newfs command fails when attempting to create a filesystem on these drives. (Note that "two-gigabyte" drives are actually slightly larger than 2GB, so that they are susceptible to this problem.) Consequently these drives may be used by partitioning with the UNIX disk command, but they cannot be used as boot devices. See NeXTanswer 1533_initializing_and_partitioning_big_disks for more information.

This has been fixed in NEXTSTEP Release 3.3.

SCSI Device Numbering

Q: How are SCSI device numbers assigned on HP hardware?

A: Unlike NEXTSTEP on NeXT and Intel-based hardware, NEXTSTEP for PA-RISC assigns SCSI device numbers in order of *decreasing* SCSI ID numbers. In other words, NEXTSTEP scans down by SCSI ID, assigning device number 0 to the first device encountered, device number 1 to the second, etc.

For example, a typical HP SCSI setup consists of a hard disk at SCSI ID 6 and a CD-ROM drive at SCSI ID 2. In this example, the hard disk is assigned SCSI device number 0, while the CD-ROM drive is assigned device number 1. A second hard disk added at ID 1 would then be assigned device number 2.

Fast-Wide SCSI Support

Q: Is the fast-wide SCSI interface supported on the higher-end HPPA workstations?

A: No, fast-wide is not supported by NEXTSTEP. There are no announced plans to support it at this time.

Video Support

Q: What video cards can I use with my HP workstation and what modes will it work in?

A: The following are the HP PA-RISC workstations and video systems supported by NEXTSTEP 3.3:

HP 712(/60 or /80)
Built-in (Artist)
RGB:888/32 using HP's Color Recovery technology
RGB:256/8

Resolution and Refresh Rate

All the HP's support the following resolution and refresh rate in Configure.app:
1280x1024 72Hz
However, on the machines with the Artist graphics system, 712(/60 or /80) and 715(/64, /80, or /100), it is possible to choose different resolutions and refresh rates during the HP boot process. The following are supported by the hardware:
1280x1024 72Hz
1024x768 75Hz
1024x768 70Hz
1024x768 75Hz Flat Panel
1280x1024 60Hz
1024x768 60Hz
640x480 60Hz
1280x1024 75Hz
1024x768 75Hz
800x600 75Hz
640x480 75Hz
Of course, you would also need a monitor that supports one on these.

NOTE: *a video memory upgrade is required for for an HP model 712 to have a resolution of 1280x1024.*

NeXTSTEP 3.2 HP-PA Precompiled Header Patch

These instructions show you how to install the precompiled header patch on computers running NEXTSTEP‰ Developer Release 3.2 for PA-RISC computers. The patch is distributed in an Installer package file named **PrecompiledHeaderPatch.pkg**.

This article has been archived and is no longer updated by Apple.

Installing Update 1 of the Precompiled Header Patch for NEXTSTEP Developer Release 3.2 for PA-RISC Computers

Precompiled headers built with NEXTSTEP Developer Release 3.2 for PA-RISC computers are incompatible with NEXTSTEP Developer Release 3.2 for NeXT and Intel-based computers, and vice versa. The precompiled header patch contains updated versions of the HeaderViewer application, C preprocessor, and precompiled headers for NEXTSTEP Developer Release 3.2 for PA-RISC computers that allow you to exchange precompiled headers with NEXTSTEP Release 3.2 for NeXT and Intel-based computers.

Caution: Make sure you install the precompiled header patch *after* you install the **DeveloperTools.pkg** and **DeveloperLibs.pkg** packages from the *NEXTSTEP Developer* CD-ROM. Otherwise, you will replace the new, compatible software from the patch with the incompatible software from the CD-ROM.

Installing the Precompiled Header Patch

Download the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.2/Precomp_Headers_HP.compressed

1. If you received the **PrecompiledHeaderPatch.pkg** file via NeXTmail‰ or another electronic source, place a copy of the file in a location where you can access it when you log in as **root**.
2. Log in as **root**. Only the superuser, **root**, can install the package. If you're not sure how to log in as **root**, see your system administrator.
3. If you received the **PrecompiledHeaderPatch.pkg** file on a floppy disk, insert the disk in the floppy disk drive. Choose Check for Disks from the Workspace Manager‰ application's Disk menu. When the disk icon appears in the File Viewer, double-click it to open it.
4. Double-click the **PrecompiledHeaderPatch.pkg** file.
5. Click the Install button in the Installer package window. When the panel asks you what kinds of computers you want to install the software for, select NeXT, Intel, and PA-RISC computers and click Install. Then click Continue in the panel that warns you you're about to overwrite existing files.
6. When the installation is complete, choose Quit from the Installer menu. The contents of the package are now installed on your computer.

For information about logging in and out, the Workspace Manager application, and the Installer application, see the *NEXTSTEP User's Guide*. For information about precompiled headers, see the NEXTSTEP Developer's Library.

DAL: Rdb Support and CPU Overhead Questions

1) Can I access multiple Rdb/VMS databases (not just tables within a database) simultaneously with DAL?

2) Approximately how much CPU power does DAL use?
This article has been archived and is no longer updated by Apple.

1) Multiple Databases

Let's go over the terminology used by Rdb/VMS as compared to parallel terminology often used in discussions of relational theory:

Rdb/VMS Term	Relational Technology Term
Relation	Table
Record	Row (Tuple)
Field	Column (Attribute)
System relations	Metadata

In Rdb/VMS, you can choose to store relations (tables) in a single file or in separate files. A database that stores relations in one file with file type RDB is a single-file database. You can also have a database in which all metadata and system information are stored in a root file (file type RDB) and the data are stored in one or more storage area files (default file type RDA). You can place each relation in a separate file, several relations in one file, or several relations in separate files. A database with a root file and one or more storage area is a multifile database.

As you can see, each database can store one or more relations (tables) in one or more files.

Data Access Language will open more than one database using the OPEN dbbrand DATABASE "databasename"statement or command. For example:

open rdb database "daldemo"

will open the "daldemo" database that contains one or more tables.

You can use another OPEN rdb DATABASE to open a new database. The newly opened database becomes the default database for the session. This means all subsequent unqualified table references refer to this database. You can, however, use the USE DATABASE dbalias to establish a previously-opened database as the current default database. Each Open Database statement requires a USE LOCATION statement if the Rdb databases are not all in the same location.

2) CPU Use

There are no rough figures on how much CPU power DAL uses because many factors affect the performance of the system. In theory, DAL overhead should be minimum compared to one imposed by the DBMS. If you monitor top CPU usage on the VAX, you will notice that percentage used by DAL server is quite low.

HP Terminal Emulators: Printing on Host Printers

Is there a Macintosh terminal emulator that allows file transfer and printing from an HP3000? I've found some information about Session and Reflection 3 PLUS, but there's no mention of printing.

I've also read that Tymlabs, publishers of the Sessions series of terminal emulators, now supports Ethernet. Will using Ethernet allow better connectivity?

This article has been archived and is no longer updated by Apple.
To our knowledge, no terminal emulation package for HP computers has a specific feature to print directly to an HP3000's printers. You'll have to use the file transfer feature to transfer the text file to the HP3000 and print from there. Walker, Richer & Quinn Inc., the maker of Reflection 3 PLUS, says that you can automate this process using their scripting language. Tymlabs Corporation, the maker of Session, said that version 4.0, has scripts for printing on the host printer.

Ethernet's high transmission speed (10 megabits per second) is particularly useful when there is heavy use of a file server. Examples include multi-user database use, primary storage use for all applications, or for applications development with shared libraries on the file server.

NeXTSTEP 3.3 Release Notes Addendum

Other Release Notes

If you have an Intel-based or NeXT computer, the *NetInstallHelper* and *RemoteUpgrade* topics in the on-line system administration release notes incorrectly describe how to prepare a site for network installation or upgrading, and how to upgrade multiple computers across the network.

This article has been archived and is no longer updated by Apple.

RemoteUpgrade
Question:

Where is the *RemoteUpgrade* utility the Release Notes on Remote Upgrades talks about for doing template upgrades? The Release Notes say to look in the root directory of the 3.3 CDROM.

Answer:

You will find the *RemoteUpgrade* utility in "/Upgrader.app/Default.upgrade". If you are using the file viewer, select Upgrader.app in the root directory with a single mouse click, then select "Open as Folder" from the Workspace menu to get a new viewer that has the Default.upgrade folder. Inside the Default.upgrade folder is the *RemoteUpgrade* utility.

NeXTTeX.pkg
Question:

Why doesn't TeX work under 3.3?

Answer:

If you select NeXTTeX.pkg to be installed during the initial installation process, it will not install properly. You must install it using /NextAdmin/Installer.app after your initial installation is complete.

You will find the NeXTTeX.pkg on your CDROM under the directory NeXTCD/Packages

See /NextLibrary/Documentation/NextAdmin/ApA_ManagerApps.rtfd for information about running Installer.app.

Printing UNIX ManPages
Question:

Why can't I print UNIX ManPages under NEXTSTEP 3.3 Intel?

Answer:

There is a bug in 3.3 with some of the files needed for printing manpages.
The files are **/usr/lib/transcript/troff.font/{Helvetica,Times}/font.ct**
Replacing these files with their 3.2 counterparts fixes the problem.

Macintosh/VAX Integration: Queue & Bridge Questions

An office has VAX computer where 90% of the firm's 350 users have terminals and some Intel-based PCs. The VAX is the hub of the entire operation.

All printing is through the print Queue mechanism on the VAX. The VAX handles forty HP LaserJet clones with PCL as the communication mechanism from the queue to the printer. The printers are serially connected with terminal servers.

1) Is there a product that allows the Macintosh to access these print queues using PCL, or does this have to be done through PostScript?

2) Remote access to this system is through VitaLink bridges. Has any headway been made to incorporate AppleTalk into these bridges? All VAX resources are on one side of the bridge, so this would eliminate DECnet encapsulation.

This article has been archived and is no longer updated by Apple.
1) We are not aware of any product that will do what you are looking for. To do this, the product must supply a receiver process on the VAX, which will act like a LaserJet printer and register its name on the network for users to choose from. Once a PCL print job is sent from the Macintosh, the receiver reads the LaserJet PCL format file and stores it as a standard VAX/VMS text file to be sent to the print queueing system. A print symbiont will take standard VMS text files and convert them to PCL format before they can be forwarded to the LaserJets. The symbiont translator is normally driven by a set of Device Control Library (DEVLIB) modules. Theoretically, one can write a Device Control Library module to translate file to PCLs.

Macintosh to VAX integration product such as PATHWORKS for Macintosh and Alisa use this above approach to get PostScript files to the VAX queue and then print on the Apple LaserWriters on LocalTalk or Digital PostScript printers on the network. Of course, the printers have to support PostScript. One way to allow printing on PCL-based printers is to write a Device Control Library module mentioned above to translate from PostScript to PCL. This is not a trivial task.

In your situation, the easiest way, though not a seamless integration, is to send the text files to the printer device captured by the VMS print queue. These are the terminal server port names in your case. On VAX/VMS, once a terminal port or a terminal server port is captured by a queue, any file sent to the port directly will be queued. The file can be sent by NetCopy application over DECnet, specifying the destination node name followed by the terminal port name, such as YOURNODE::LTA12:, where LTA12 is the terminal server port connected to the LaserJet. You might want to check if the port protection is world write-able. Doing this way, there is no change required in their current PCL-based printer queues.

2) In theory, bridges will pass all protocols on the network unless you program them to filter a particular protocol. To our knowledge, the VitaLink bridge should pass AppleTalk protocol. You should check with Network Systems (formerly VitaLink) for the correct hardware and software version, and correct configuration to pass AppleTalk protocol.

NeXTSTEP: Encoding Foundation Classes With Distributed Objects

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

Question

How do I encode NSObject subclasses over-the-wire with Distributed Objects since NSObject does not implement the NXTransport protocol? I have an application that uses some Foundation objects with Distributed Objects. Do any Foundation classes implement the NXTransport protocol? If not, how can I encode Foundation objects over the wire?

Answer

Sending NSObjects "by reference" or "by proxy"

Sending NSObjects by reference was not supported in the foundation shipped with NEXTSTEP 3.3 and EOF 1.0. However, this is supported in the foundation included with EOF 1.1.

EOF 1.1 includes the NXAutoreleaseConnection class, that will ensure that autoreleased objects are correctly released in non-appkit servers. However, NXAutoreleaseConnection's **connectToName:onHost:** still returns a retained object. Thus, once the client is finished with the object returned by **connectToName:onHost:**, it must send **release** or **autorelease** to it.

Sending NSObjects "by value" or "by copy"

In order to send an object over-the-wire "by value" or "bycopy" you need to implement the NXTransport protocol. However, NSObject itself does not implement the NXTransport protocol, so no NSObject subclasses can implement it. As a result, NSObject subclasses cannot be encoded bycopy.

However by substituting an Object for the NSObject during the encoding process, it is possible to achieve the same result as encoding the NSObject bycopy. When encoding an object bycopy, the DO system does the following:

· Sends the object to be encoded an **encodeRemotelyFor:freeAfterEncoding:isBycopy:** message, and keeps the return value.
· Sends that return value the **encodeUsing:** message to encode it over the wire.
· In the receiver, an instance of the class that was encoded is created with alloc/init and it is sent a **decodeUsing:** message.
· The object returned by **decodeUsing:** is passed to the receiver of the DO message.

With categories on NSObject and it's subclasses, it is possible to return a placeholder object

from **encodeRemotelyFor:freeAfterEncoding:isBycopy:**, the placeholder object gets encoded over the wire, and then it can return the appropriate NSObject subclass from it's decodeUsing: implementation. If the placeholder object is an Object subclass, it can implement the NXTransport protocol with no problem.

The NSString, NSNumber and NSData classes in Foundation already implement the NXTransport protocol in this fashion so that they can be sent bycopy with no code changes. For example you can encode and decode these objects with the **encodeObject:** and **decodeObject:** methods as you would any other object. For the other Foundation classes, a category must be be added to provide this functionality.

Valid for: EOF 1.0, EOF 1.1, NEXTSTEP 3.2, NEXTSTEP 3.3

MacTerminal 3.0: Block Cursor Disappears on Macintosh LC

I'm using MacTerminal 3.0 on a Macintosh LC with System 6.0.7. My block cursor disappears off the screen when logged onto the VAX using VT320 emulation. I have to go into the terminal settings dialog to get the cursor to show up again.

Are there any compatibility problems with MacTerminal and the Macintosh LC?

This article has been archived and is no longer updated by Apple.
We tried both the LAT Tool over Ethernet and the Serial Tool to the VAX, but were unable to duplicate the problem. We don't know which Connection Tool you're using, but here are a few suggestions:

1) Throw away the old system file and reinstall it.

2) Throw away the Communications folder, reinstall the CommToolBox and its Tools from a known good copy of the diskette.

3) Make sure that you don't have any other INITs/CDEVs in the system that may conflict.

4) We have heard that some network devices that provide serial look-alike drives are having problems with the CommToolBox. If you're using one of these drivers, remove it and try MacTerminal again.

NeXTSTEP 3.3 Driver: MediaVision Jazz16

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.30, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/MedVisionJazz16.pkg.compressed

Driver Name / Installer .pkg: MVJazz16AudioDriver
Driver Type: Sound
Driver Scope: Product Family
Supported Components: Media Vision Jazz16
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This driver is intended to support several Jazz16 chipset based cards and motherboards implementations.

Supported Products / Add-on Adapters:
Media Vision Deluxe Sound Card
Media Vision Pro Sonic Sound Card

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Sound Driver Details

Supported Connectors: 1/8" Microphone In, 1/8" Stereo Line-In, 1/8" Stereo Line-Out, 1/8" Stereo Speaker , CD-ROM Stereo Line-In
Access Mode: DMA
Adapter Memory: N/A
Attributes: 16-bit Linear, 8-bit Linear

Known Problems

Mixer (part no. MVA508) in Media Vision Premium 3-D adapter is currently unsupported.

NeXTSTEP 3.3 Driver: ATI Mach64

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.37, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/ATI_Mach64.pkg.compressed

Driver Name / Installer .pkg: ATIMach64DisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: ATI 88800 (Mach64)
PC Bus / Interface Supported by Driver:** Integrated, PCI, VL-Bus

General Overview notes: This new graphics driver is designed to support a variety of graphics adapters using the ATI 88800 graphics controller. Adapters based on the 88800 GX/CX (also known as the Mach64) graphics controller chipset can support 1MB, 2MB or 4 MB of VRAM or DRAM. This driver supports a variety of configurations including high-resolution and high-color (32bit) modes and several RAMDAC, frame buffer and interface bus (PCI and VL-Bus only) configurations.

Due to the wide range of possible combinations, only a few specific adapters will be tested by NeXT. Although this driver may work with most 88800 GX/CX based adapters, NeXT will only support the specific adapters tested by NeXT.

Supported Products / Add-on Adapters:
ATI Graphics Ultra Pro Turbo (PCI, with 2MB VRAM)
ATI Graphics Ultra Pro Turbo (PCI, with 2MB DRAM)
ATI Graphics Ultra Pro Turbo (PCI, with 4MB VRAM)
ATI Graphics Ultra Pro Turbo (PCI, with 4MB DRAM)
ATI Graphics Ultra Pro Turbo (VL-Bus, with 4MB VRAM)
ATI Graphics Ultra Pro Turbo (VL-Bus, with 4MB DRAM)

Supported Products / Systems (ie integrated into PC System):
AT&T Globalyst 600

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB DRAM, 2MB VRAM, 4MB DRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
640x480 (4MB+), 800x600 (4MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 1152x896 (2MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1152x896 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 800x600 (1MB+)

Known Problems

The Mach64 driver makes use of the board's BIOS to switch modes. This requires the user to set up the display adapter as specified in the documentation supplied by ATI. This will usually require running a setup utility. Until this is done, not all supported display modes will be available.

Driver Version Notes

3.33 Added support for additional hardware
3.34 Added support for ATI 68860 Rev C and ST1703 RAMDACs.
3.36 Beta - Driver rewritten to call Adapter's BIOS to switch modes.
3.37 First Released version that uses the Adapter's BIOS - should be robust to RAMDAC changes.

NeXTSTEP 3.3 Driver: S3 Generic

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/S3_Generic.pkg.compressed

An updated BETA version of this driver, version 3.33, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/S3GenericDisplay.pkg.compressed

Driver Name / Installer .pkg: S3GenericDisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: S3 732 (Trio32), S3 764 (Trio64), S3 764 (Trio64V+), S3 801, S3 805, S3 864 (Vision), S3 868 (Vision), S3 911
PC Bus / Interface Supported by Driver:** Integrated, PCI, VL-Bus

General Overview notes: This driver will support a variety of video display devices based on S3 chipsets. It is primarily intended to support implementations based on the S3 Vision864, Vision868, ViRGE, though it should also support many adapters based on other S3 products such as the Vision964, Vision968, Trio32, Trio64, & ViRGE/VX chips.

This driver is a generic chipset driver and as such, is only intended to be used as a last resort. If a driver is available that specifically supports your display adapter, that driver should be used rather than this generic driver.

NeXT does not guarantee that this driver will work with any specific adapters or implementations, but expects that it will support many.

1024x768 (1MB+), 1280x1024 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.33) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.32 Added support for the Trio64V+ chipset
3.33 Added support for the ViRGE chipsets

AppleTalk Phase II: Issues with FDDI Are Resolved

Is there an issue with AppleTalk Phase 2 and FDDI?
This article has been archived and is no longer updated by Apple.
The IEEE 802.1h is the formal standard for AppleTalk and FDDI. Below are four third-party vendors which support this standard:

- UB Networks' current products supports the 802.1h standard. Users should contact them regarding their bridges and for upgraded information.
- 3Com Corporation's LANPlex bridge supports the 802.1h standard and AppleTalk. For more information see the following web page: **http://www.3com.com/cgi-bin/mfs/01/0files/products/dsheets/lpfamspc.html**
- Kalpana's EtherSwitch supports 802.1h.
- Grand Junction's FastSwitch supports 802.1h.

We believe there are other bridges that support 802.h as well.

Below Is Information Outlining Issue Before The IEEE 802.1h Was Set
---
First, some background:

AppleTalk Phase 2 packets crossing a transparent FDDI bridge are translated into Ethernet-style packets. If these packets translate incorrectly, the bridged Ethernet segments can't communicate with each other over EtherTalk Phase 2. This problem relates to the way vendors implement the OUI 0000 (organizational unique identifier) in the 802 SNAP header.

Some bridge vendors base their products on the IEEE 802.1 standard. However, there are questions about how the standard handles translating "all zeros" in the OUI field of an 802.2 SNAP header.

The problem has to do with the way Apple implements AARP in SNAP in AppleTalk Phase 2. The 802.1 specification says that all SNAP PDUs need a 40-bit protocol identifier. The first 24 bits are unique organizational identifiers assigned by the IEEE; the remaining 16 bits are administered by the assignee:

```
              UI              Assignee Administered
   0011 0101 0111 1011 0001 | 0010 0000 0000 0000 0001
   |  |
lsb msb

Apple's assigned identifier is    08   00   07
                                  1000 0000 0111
             network bit order    0001 0000 1110
                                  ||
IEEE 802.1 states that:           ||
                                  MX

             M = 0: (M=1 is reserved)
             X = 0: Globally Administered Protocol Identifier
             X = 1: Locally Administered Protocol Identifier
```

For all AppleTalk protocols, Apple uses the identifier 08007809B. But for AARP, Apple uses 00000080F3. This is really where the problem begins--in the use of OUI 00000.

Because Apple uses 0000 as a UI, there are conflicts with FDDI-Ethernet bridges that also use the same UI to recognize and translate Ethernet-style packets. The question is: who's right--Apple, the vendor, or both?

The all-zero OUI was not intended to be used for translating Ethernet frames to 802.2/SNAP. Its original intention was (and is) not completely clear; all that was agreed upon was:

1) The low-order 16 bits of the SNAP protocol discriminator indicated an Ethernet protocol type; and

2) The format of the data part of the SNAP packet was the same as the format of the data part of the Ethernet packet of this protocol type.

This "general agreement," was never written down--AppleTalk Phase 2 and TCP/IP just adopted it. Unfortunately, on an Ethernet/802.3 data link, AppleTalk Phase 2 runs on top of 802.3 (and 802.2) and TCP/IP runs on top of Ethernet. Thus, when TCP/IP Ethernet nodes communicate with TCP/IP 802.2 nodes (on token ring or FDDI, say) some type of packet translation must occur. But AppleTalk Phase 2 Ethernet nodes

communicating with AppleTalk Phase 2 802.2 nodes (on Ethernet, token ring or FDDI) MUST NOT have any translation done.

This is why it's not so simple to build a bridge that "transparently" allows both forms of communication. What's needed is a bridge with a small Ethernet protocol translation table. The smaller the table, the less translation that happens, and the better the bridge's performance. Any bridge between Ethernet and 802 media that does not translate OUI zero packets prevents TCP/IP nodes (and any others using the same OUI convention) from communicating between the two media. Any bridge between Ethernet and an 802 media that translates all OUI zero packets prevents AppleTalk nodes (and any others with an OUI of zero who don't expect translation) from communicating between the two media. In both cases, routers can, of course, be set up to communicate.

A similar problem happens if two bridges connect two Ethernet/802.3 data links across an 802 backbone (say FDDI). In this case, some type of translation/encapsulation of Ethernet (non-802.3) packets must happen so they can pass across the 802 backbone. There are many ways to do this, one of which is to translate all Ethernet packets to OUI zero packets, shipping them across the backbone, and then converting them back. This, however, does not work for any OUI zero packets that start out on the Ethernet/802.3 data link. Such packets will not be translated on the way into the backbone but will be incorrectly translated before being delivered on the destination Ethernet. Such packets should be forwarded entirely without translation.

In terms of actual product implementations, unfortunately DEC is already shipping an Ethernet-to-FDDI bridge (LanBridge 500) that translates all OUI zero packets, and thus does not work with AppleTalk Phase 2. DEC is aware of this issue. At the recent 802 meetings in Denver, it was clear that this type of translation is not part of the 802.1d (Mac Bridging) standard, but is something that many bridge manufacturers wish to include as a non-802-standard option with their products. Most have said they will have some type of translation (or non-translation) table to ensure it is possible to work with all known protocols.

Current Status:
At a recent IEEE 802.1 meeting, there was agreement about the translation of Ethernet-like packets from an FDDI backbone to an Ethernet segment. The creation of a new OUI for Ethernet (non 802.3) packets will be required. The Bridge translation decision from an FDDI backbone to Ethernet segment will be as follows:

If OUI = NEW, then translate back to Ethernet (e.g., Phase 1
EtherTalk) Otherwise if (OUI=0 and TYPE=80F3 or other defined types do
NOT translate), Do not translate (e.g., Phase 2 EtherTalk AARP)

Apple and DEC were major sponsors of this proposal, and DEC has agreed to make changes to their bridges. This means is that EtherTalk Phase 2 AppleTalk end nodes will work correctly (without modification to the end nodes), when transversing an Ethernet/FDDI bridge. Furthermore, EtherTalk phase 1 end nodes will also work using the new OUI translation scheme.

The IEEE 802.1 committee is currently formalizing the use of OUI in Ethernet to FDDI bridges that will define what to do if a bridge encounters SNAP headers with OUI=0.

NeXTSTEP 3.3 Driver: Intel 82596 Network

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.33, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/Intel82596Net.pkg.compressed

Driver Name / Installer .pkg: Intel82596NetworkDriver
Driver Type: Networking
Driver Scope: Product Family
Supported Components: Intel i82596
PC Bus / Interface Supported by Driver:** EISA, PCI

General Overview notes: This driver supports adapters based on the Intel 82596 chipset.

Supported Products / Add-on Adapters:
Intel EtherExpress PRO/10 PCI (PILA8400) (BNC, UTP, AUI)
Intel EtherExpress PRO/10 PCI (PILA8420) (UTP)
Intel EtherExpress Flash32 EISA (EILA8225) (BNC, UTP, AUI)
Cogent eMaster EM935 EISA XL (BNC, UTP, AUI)
Cogent eMaster EM932 EISA (UTP, AUI)
Cogent eMaster EM932 EISA (BNC, UTP, AUI)
Cogent eMaster EM945 EISA FDE (BNC, UTP, AUI)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This driver obsoletes CogentEMaster

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Networking Driver Details

Network Type:** EtherNet
Speed*: 10 Mb/s
Access Mode:** Bus Master DMA
Buffer Size*: N/A
Supported Connectors:** AUI, BNC, UTP

Known Problems

More than one instance of the adapter is autodetected in Configure.app.
The full-duplex feature of the Cogent EM945 FDE adapter was not tested.

Driver Version Notes

3.31 - First release of this driver
3.33 - Added support for EE PRO/10 PCI

NeXTSTEP 3.3 Driver: AMD PC SCSI

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.36, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/AMD_PC_SCSI.pkg.compressed

Driver Name / Installer .pkg: AMD53C974SCSIDriver
Driver Type: SCSI
Driver Scope: Generic-Chipset
Supported Components: AMD Am53C974, AMD Am79C974
PC Bus / Interface Supported by Driver:** Integrated, PCI

General Overview notes: This driver should support the AMD Am53C974 family of PCI SCSI controllers. The 79C974 is a combo chip with contains an Am79C970 ethernet core and an Am53C974 SCSI core

Supported Products / Add-on Adapters:
The AMDPCSCSI driver is known to work with the following SCSI devices:
Toshiba CD-ROM XM-3401T
Peripheral Solutions 8mm Exabyte DAT Drive -- 8500
Syquest 88MB SQ5110 D3G 810
IOMEGA Bernoulli 230 BETA230 1.1408/2
Pinnacle Micro Tahoe 230MB MO J6CTahoe-130A

Driver Name / Installer .pkg: SYM53c8
Driver Type: SCSI
Driver Scope: Generic-Chipset
Supported Components: NCR/SYM53c810, NCR/SYM53c815, NCR/SYM53c820, NCR/SYM53c825
PC Bus / Interface Supported by Driver:** Integrated, PCI

General Overview notes: This driver supports the NCR 53C8xx family of SCSI controllers.

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):
DEC Celebris XL/590

Special Features of Driver / Driver Notes:
Cmd queuing is disabled. Synchronous and wide data transfers are selectable through the Configure panel. Support for multiple adapters.

Suggest upgrading Symbios BIOS to version 3.07. Some systems have experienced a hang during initialization on previous BIOS versions.

SCSI Driver Details

Supported Connectors: 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2), 68-pin High Density (Wide SCSI)
Access Mode:
Attributes:** SCSI-2
Cache Size Supported:**

Driver Name / Installer .pkg: Wingine64300DisplayDriver
Driver Type: Display
Driver Scope: Specific Product
Supported Components: C&T 64300 (Wingine)
PC Bus / Interface Supported by Driver:** Integrated

General Overview notes: This driver supports the Wingine 64300 Display chipset on the NEC PowerMate 466D.

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):
NEC Powermate 466D

Special Features of Driver / Driver Notes:
The RAMDAC used in this system supports a Color Palette only in 8 bit modes. This results in the brightness slider in Preferences, as well as automatic screen dimming, only working if an 8 bit mode is selected.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 2MB DRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**

16 Bit Color Modes:**
640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1120x832 (1MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

SoftPC will generate an illegal instruction error when switching to full screen mode.

Driver Name / Installer .pkg: EtherLink3
Driver Type: Networking
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver:** EISA, ISA

General Overview notes: This driver supports the 3COM EtherLink III Ethernet Adapter.

Supported Products / Add-on Adapters:
3Com EtherLink III 3C509 ISA (BNC, AUI)
3Com EtherLink III 3C509B ISA (BNC, AUI)
3Com EtherLink III 3C509-TP ISA (RJ-45, AUI)

3Com EtherLink III 3C589C-TP (RJ-45)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
NeXTanswer#1482_3COM_Etherlink_III_Ethernet_Adapter.rtf does not apply to versions 3.31and later of this driver.

Networking Driver Details

Network Type:** EtherNet
Speed*: 10 Mb/s
Access Mode:** Memory Mapped
Buffer Size*: 8KB
Supported Connectors:** AUI, BNC (10Base-2), RJ-45 (10Base-T)

Known Problems

Driver Version Notes

3.31 Significant performance improvements; added support for the 3C589 PC Card (PCMCIA) adapter
3.33 Added support for EtherLink III PnP boards in Plug and Play mode. Removed the connector selection logic from the driver: the driver now pays attention to the values configured via 3c5x9cfg.exe provided on the 3Com setup diskette.

NeXTSTEP 3.3 Driver: Adaptec 154x Family And Compatible SCSI

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

NEXTSTEP for Intel Processors Release 3.3

SCSI Driver Overview

Driver: Adaptec 154x family and compatible
Driver Overview: NeXTanswer #1758
Last Update: April 23, 1997

Availability Information

An updated release version of this driver, version 3.35, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/Adaptec1542BSCSI.pkg.compressed

Driver Name / Installer .pkg: Adaptec1542B
Driver Type: SCSI
Driver Scope: Product Family
Supported Components: Adaptec AIC-6251, Adaptec AIC-7970
PC Bus / Interface Supported by Driver:** EISA, ISA

General Overview notes: The Adaptec154x compatible driver is designed to support a variety of SCSI adapters from Adaptec and several third parties.

Supported Products / Add-on Adapters:
Adaptec 154xB (ISA)
Adaptec 154xC (ISA)
Adaptec 154xCF (ISA)
Adaptec 174x (EISA) in standard 154x mode only

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
The onboard floppy controller, available on the 1542 cards, is not supported.

SCSI Driver Details

Supported Connectors: 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2)
Access Mode: DMA
Attributes:** SCSI-2
Cache Size Supported:** N/A

Known Problems

· For setup and installtion of the 154xB see
NeXTanswers document number 1107.

· For setup and installtion of the 154xC/CF see
NeXTanswers document number 1108.

· NEXTSTEP does not officially support the floppy controller integrated into the 1542B. Use the floppy controller integrated into your system's motherboard.

· When installing NEXTSTEP onto an IDE hard disk drive, the CD-ROM drive's SCSI ID number should be zero.

· Some users have reported problems during the installation process if the CD-ROM drive's SCSI ID number is set to zero. NEXTSTEP will freeze after displaying the message rootdev 608 when this problem is encountered. Setting the CD-ROM drive's SCSI ID to six has fixed the problem when nothing else seemed to work.

· Improper SCSI termination can cause strange, unreproducible errors. Be certain that the first and last devices on the SCSI bus (and only these two devices) are terminated.

· Avoid system configurations combining an Adaptec 154xB/C/CF and an ATI Ultra Pro EISA card. A hardware conflict exists which causes data corruption on SCSI hard disks.

· If your system includes an Adaptec 1542B and you do not have jumper six enabled it will hang. It will boot off the floppy and recognize the SCSI drives, but instead of starting the install process, it will hang with the messages:

fdisk: bogus bios info
some bios' can't handle non-sequential targets.

· The Adaptec 1542B does not support 2.88MB floppy drives attached as SCSI devices.

Driver Version Notes

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

NeXTSTEP 3.3 Driver: Adaptec 274x And 84x Family SCSI

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/Adaptec2740SCSI.pkg.compressed

Driver Name / Installer .pkg: Adaptec2740
Driver Type: SCSI
Driver Scope: Product Family
Supported Components: Adaptec AIC-7770
PC Bus / Interface Supported by Driver:** EISA, VL-Bus

General Overview notes: The Adaptec 274x series driver is designed to support the 274x series of EISA SCSI adapters and the 284x series of VL-Bus SCSI adapters. The 2(7,8)42 versions include a floppy controller.

Supported Products / Add-on Adapters:
Adaptec 2740 (EISA) - not tested but should work
Adaptec 2740T (EISA)
Adaptec 2840 (VLB)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
The 274x is available in a 'T' version that includes two SCSI channels, both channels are supported by this driver.

The onboard floppy controller available on the 2(7,8)42 cards is not supported.

SCSI Driver Details

Supported Connectors: 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2), 68-pin High Density (Wide SCSI)
Access Mode: DMA
Attributes:** SCSI-2
Cache Size Supported:** N/A

Known Problems

The 284x driver uses port 4c00 by default. You must set the DIP switches on your 284x card to use this port. The correct settings are:
sw1:on
sw2:on
sw3:off
sw4:off

The 274x driver uses port 0x4c88 by default.

NeXTSTEP 3.3 Driver: Adaptec 2940 Family And 7870 Integrated SCSI

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.37, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/Adaptec2940SCSI.pkg.compressed
An updated BETA version of this driver, version 3.39, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/Adaptec2940SCSI.pkg.compressed

Driver Name / Installer .pkg: Adaptec2940SCSIDriver
Driver Type: SCSI
Driver Scope: Product Family
Supported Components: Adaptec AIC-7850, Adaptec AIC-7870, Adaptec AIC-7870D, Adaptec AIC-7880
PC Bus / Interface Supported by Driver:** Integrated, PCI

General Overview notes: The Adaptec 2940 series driver is designed to support the 2940 series of PCI SCSI adapters.

Supported Products / Add-on Adapters:
Adaptec AHA-2930B (PCI)
Adaptec AHA-2940 (PCI)
Adaptec AHA-2940W (PCI, Wide SCSI)
Adaptec AHA-2940U (PCI, Ultra SCSI)
Adaptec AHA-2940UW (PCI, Ultra/Wide SCSI)
Adaptec AHA-2910B (PCI) - Not tested but should work.

Supported Products / Systems (ie integrated into PC System):
DEC EISA/PCI Server system w/ 7870 on motherboard
DEC Celebris GLST w/ 7850 on riserboard
HP Kayak on-board 7860 & 7880 based SCSI adapters.

Special Features of Driver / Driver Notes:
This driver does not support the Adaptec AHA-2920 (PCI)

SCSI Driver Details

Supported Connectors: 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2), 68-pin High Density (Wide SCSI)
Access Mode: Bus Master DMA
Attributes:** SCSI-2
Cache Size Supported:** N/A

Known Problems

The Adaptec 2940 SCSI Host Adapter Driver supports Synchronous Data Transfer as well as Fast SCSI transfers. In order to enable Synchronous Data Transfer, this feature must be enabled in both the 2940's AutoSCSI program and in the NEXTSTEP Configure application, when configuring the Adaptec 2940 driver. In the AutoSCSI program, this feature is enabled in the SCSI Device Configuration menu, via the Initiate Sync Negotiation field. This can be enabled or disabled on a per-target basis. In the Configure application, the Synchronous button, if disabled, disables Synchronous Transfers for ALL targets. If enabled, the values selected in the AutoSCSI program are used to determine whether or not Synchronous Transfers occur on a per-target basis.

The Synchronous Transfer data rate is determined in the 2940's AutoSCSI program, via the Maximum Sync Transfer Rate field in the SCSI Device Configuration menu. Fast SCSI Transfers are enabled by selecting a value of 10 (i.e., 10 Megabytes/seconds) for this field. Note that if Synchronous Transfers are disabled, the Maximum Sync Transfer Rate field is meaningless. Also note that it is not recommended to select a value higher than 5 for a device which is in an external enclosure and connected to the 2940 via an external SCSI cable.

Driver Version Notes

3.33 Added support for Adaptec's AIC-7850 chipset
3.36 Added support for Adaptec's AIC-7870 revision D (needed to support the latest revisions of the AHA2940 & AHA2940W)
3.37 Integrated Adaptec's HIM v1.21 to support the AHA2940U & AHA2940UW Ultra SCSI host adapters
3.39 Fixed a bug which prevented adapters with BIOS rev. 1.32 from working on machines with Phoenix BIOS

Supported Components: Adaptec AIC-6360
PC Bus / Interface Supported by Driver:** Integrated, ISA

General Overview notes: The Adaptec 6x60 Compatible SCSI driver is designed to support a variety of SCSI adapters which incorporate the Adaptec 6260 & 6360 SCSI controller chipsets.

Supported Products / Add-on Adapters:
Adaptec AVA-1505A (ISA)
Adaptec AVA-1515A (ISA)
Adaptec AHA-1520A (ISA)
Adaptec AHA-1530P (ISA) - Not tested but might work.
Adaptec Slim SCSI (PC/MCIA)

Supported Products / Systems (ie integrated into PC System):
Intel GX/Pro

Special Features of Driver / Driver Notes:
The onboard floppy controller, available on some cards, is not supported.

SCSI Driver Details

Supported Connectors: 25-pin DB25 (Mac SCSI), 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2)
Access Mode: PIO
Attributes:** SCSI-2
Cache Size Supported:** N/A

Known Problems

Never tested with Compaq Portable 486/M,C and does not work.
Next SCSI color printer currently does not work with the Adaptec 6x60 driver.

Driver Version Notes

3.32 Adds support for Adaptec Slim SCSI (PC/MCIA) and SoundBlaster 16 integrated SCSI.

NeXTSTEP 3.3 Driver: AMD PCnet32

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.30, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/AMDPCnet32.pkg.compressed

Driver Name / Installer .pkg: AMDPCnet32NetworkDriver
Driver Type: Networking
Driver Scope: Generic-Chipset
Supported Components: AMD Am79C965, AMD Am79C970, AMD Am79C974
PC Bus / Interface Supported by Driver:** Integrated, PCI, VL-Bus

General Overview notes: This driver is designed to support LAN adapters that use the AMDPCnet32 ethernet controller. The AMD PCnet32 Ethernet controller is used in both integrated designs (on-board system boards or accessory daughter cards) and add-on VL-Bus and PCI adapters. This NEXTSTEP driver is designed to support generic implementations of the AMD Am79C965 and Am79C970 chipset (ie designs that follow the example design as provided by AMD). The 79C974 is a combo chip with contains an Am79C970 ethernet core and an Am53C974 SCSI core

Supported Products / Add-on Adapters:
X/Lan Add-On Adapter (based on Am79C970)

Supported Products / Systems (ie integrated into PC System):
Canon object.station 41
Compaq Deskpro XL (On-board)
HP Vectra XU (On-Board)

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Networking Driver Details

Network Type:** EtherNet
Speed*: 10 Mb/s
Access Mode:** Bus Master DMA
Buffer Size*: N/A
Supported Connectors:** AUI, UTP

Known Problems

The 3.30 version of the driver will sometimes exhibit extremely poor performance on some systems. Due to reliability issues, it is not recommended that you use the this driver with the HP Vectra XU machines.

IBM PCI Ethernet Adapter (based on Am79C970, IBM part #13H9237) is reported to work but has not been tested by SQA.

Driver Version Notes

3.33: Added support for an updated version of PCnet32 PCI hardware.

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

NeXTSTEP 3.3 Driver: ATI Generic

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: ATI
Driver Type: Display
Driver Scope: Product Family
Supported Components: AT&T ATT20C491 RAMDAC, ATI 68800 (Mach32), ATI 68830 RAMDAC, ATI 68875 RAMDAC, Brooktree Bt481 RAMDAC, Brooktree Bt485 RAMDAC
PC Bus / Interface Supported by Driver:** EISA, Integrated, VL-Bus

General Overview notes: This driver is obsolete and has been replaced by ATIMach32. See NeXTanswers #1817_ATI_Mach32_Driver_Overview.rtf

The ATI graphics driver is designed to support the ATI 68800 graphics controller (also known as Graphics Ultra Pro or Mach 32). Although ATI makes a broad range of graphics controllers, only the 68800 supports the linear frame buffer mode required by NEXTSTEP for 32-bit,16-bit color or 8-bit grayscale. This driver supports EISA, custom LocalBus and VESA LocalBus versions of 68800 graphics adapters. This driver also supports a variety of RAMDAC's used with these chips. Although ATI has set some standards for choice of RAMDAC, this driver should only be expected to work with the specific systems and adapters listed. Note: ATI is in the process of updating the 68800 from Rev 3 to Rev 6A. Although the Rev 6A chip is designed to be compatible with Rev 3 drivers, this driver update will be tested with Rev 3 and Rev 6A chips.

Supported Products / Add-on Adapters:
ATI Graphics Ultra Pro (EISA, ATI 68875 RAMDAC)
ATI Graphics Ultra Pro (EISA, TI 34075 RAMDAC)
ATI Graphics Ultra Pro (VL-Bus, ATI 68875 RAMDAC)

Supported Products / Systems (ie integrated into PC System):
Intel GX/Pro (Custom LB, onboard ATI, TI 34075 RAMDAC)
Data General Dasher DE2 (Custom LB, TI 34075 RAMDAC)
AST Premmia 4D (Custom LB, onboard ATI, BT 481 RAMDAC)
Gateway V Series (VL-Bus, ATI 68875 RAMDAC)

Special Features of Driver / Driver Notes:

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB VRAM, 2MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**

16 Bit Color Modes:**
1024x768 (2MB+), 1120x832 (2MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1120x832 (1MB+), 1280x1024 (2MB+), 800x600 (1MB+)

Known Problems

See Also:
1122_ATI_Ultra_Pro_Graphics_Adapter.rtfd

The ATI Ultra Pro driver reserves a large number of I/O ports to accomodate SoftPC in full-screen mode. Some of these ranges may conflict with other drivers. In particular, the range 0x52eee-0xfeef may be a problem. This conflict can be resolved simply by removing this reserved range from the driver configuration. Note, however, that this may prevent SoftPC from running correctly in full screen mode. The procedure to remove the port range is as follows:
- run Configure.app and select the display driver
- select the Expert options for the driver
- find the I/O Ports entry and double-click on the values to edit them
- scroll the field all the way to the right and delete the range 0x52ee-0xfeef. Make sure to hit return after editing, or the change won't be made.
- save the configuration and reboot

NeXTSTEP 3.3 Driver: BusLogic Family SCSI

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/BusLogicSCSI.pkg.compressed

Driver Name / Installer .pkg: BusLogicSCSIDriver
Driver Type: SCSI
Driver Scope: Product Family
Supported Components: BusLogic BA90C30
PC Bus / Interface Supported by Driver:** EISA, ISA, PCI, VL-Bus

General Overview notes: The BusLogic SCSI driver is designed to support the 747C and 445C series SCSI adapters from BusLogic. This driver is specifically designed to support the 32bit extended modes supported by these adapters. In comparison to the Adaptec 154x compatible mode previously used to support the 747S and 445S adapters, these extended modes provide additional performance, and remove the double buffering required by the16MB address limitation. This driver may work with other versions of BusLogic SCSI adapters such as the 545C, 747S and 445S. Since these adapters are supported in Adaptec compatibility mode with the existing Adaptec 154x driver, this driver will only be tested and supported on the latest generation, higher performance 747C and 445C series adapters. Note: In general this driver was designed to work with any BusLogic bus master SCSI adapter.

Supported Products / Add-on Adapters:
BusLogic 546C ISA SCSI Host Adapter
BusLogic 747C EISA SCSI Host Adapter
BusLogic 445C VL-Bus SCSI Host Adapter
BusLogic 946C PCI SCSI Host Adapter (rev C and D only)
BusLogic 948 PCI SCSI Host Adapter (not tested, reported to work)
BusLogic 958 PCI Wide SCSI Host Adapter (not tested, reported to work)

Supported Products / Systems (ie integrated into PC System):
Canon object.station 41

Special Features of Driver / Driver Notes:
The onboard floppy controller, available on some cards, is not supported.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

SCSI Driver Details

Supported Connectors: 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI)
Access Mode: DMA
Attributes:** SCSI-2
Cache Size Supported:** N/A

Known Problems

BusLogic firmware revs. before 4.25J may not work with this driver. In particular, firmware version 4.21 had a bug, which caused the Read Capacity data to be read up incorrectly.

BusLogic 946C rev A and B do not work with our driver.

NeXTSTEP 3.3 Driver: Diamond Stealh64

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: DiamondStealth64DisplayDriver
Driver Type: Display
Driver Scope: Product Family
Supported Components: S3 964 (Vision)
PC Bus / Interface Supported by Driver:** PCI, VL-Bus

General Overview notes: This graphics driver is designed to support the VL-Bus & PCI versions of the Stealth 64 Graphics adapters from Diamond Computer Corp. These cards are based on the S3-964 graphics controller chipsets and support 2MB or 4 MB of VRAM. This driver supports both configurations including a variety of high-resolution and high-color (32bit) modes. DRAM-based cards are not supported.

The current version of this driver, which is present on the NEXTSTEP 3.3 CD-ROM, is v3.30

Supported Products / Add-on Adapters:
Diamond Stealth 64 (PCI, 4MB VRAM)
Diamond Stealth 64 (PCI, 2MB VRAM)
Diamond Stealth 64 (VL-Bus, 4MB VRAM)
Diamond Stealth 64 (VL-Bus, 2MB VRAM)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This driver also works with the Spider Tarantula 64PCI display adapter

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB VRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
1024x768 (4MB+), 1152x864 (4MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 1152x864 (2MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 800x600 (1MB+)

Known Problems

· Diamond has changed the PCI deviceID on their newer Stealth adapters. This will cause autodetection to fail, thus the NEXTSTEP driver will defualt to VGA display mode. Under NEXTSTEP 3.3, the workaround is to click Expert... while inspecting the driver in Configure.app, then modify the value of the Auto Detect setting to read 0x88d05333 0x88d15333 0x88f05333.

· Diamond has produced new versions of the Stealth64 which use different S3 video controllers. Version 3.31 (or later) of

the DiamondStealth driver is needed to support these cards.

· Diamond Stealth 64 Series 2001 does not use an S3 controller, it uses the ARK Logic which is not supported.

NeXTSTEP 3.3 Driver: DPT 2000 Family SCSI

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: DPT2000SCSIDriver
Driver Type: SCSI
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver:** EISA, Integrated, ISA, PCI

General Overview notes: This driver is obsolete and has ben replaced by the DPTSCSIDriver. See NeXTanswer #1830_DPT_SCSI_family_Driver_Overview

The DPT 2000 Series driver update is designed to support the 2000 series of SCSI adapters from DPT. This driver specifically supports the DPT 2012 EISA, 2021 ISA, 2022 EISA, 2122 EISA Adapters. This driver does not support the DPT 2011 ISA Adapter. This driver replaces the NEXTSTEP 3.2 DPT 2012-B EISA SCSI Adapter driver.

Supported Products / Add-on Adapters:
DPT 2021/9x SmartCache III (ISA) - not tested, but should work
DPT 2022/9x SmartCache III (EISA)
DPT 2122/9x SmartCache III (EISA)
DPT 2122/9xW SmartCache III (EISA, Wide) - not tested, but should work
DPT 2122/9xDW SmartCache III (EISA, Differential, Wide) - not tested, but should work
DPT 2024 SmartCache III (PCI) - In future update
DPT 2124 SmartCache III (PCI) - In future update

Supported Products / Systems (ie integrated into PC System):
NEC Express II P60 (On-Board)

Special Features of Driver / Driver Notes:

SCSI Driver Details

Supported Connectors: 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2), 68-pin High Density (Wide SCSI)
Access Mode:
Attributes:** SCSI-2
Cache Size Supported:** 16MB, 4MB, 64MB

NeXTSTEP 3.3 Driver: EISA Bus

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/EISABus.pkg.compressed
An updated BETA version of this driver, version 3.36, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/EISABus.pkg.compressed

Driver Name / Installer .pkg: EISABus
Driver Type: System
Driver Scope: Generic-System
Supported Components:
PC Bus / Interface Supported by Driver:**
Supported Connectors:
Access Mode:
Adapter Memory:

General Overview notes: This is a required driver that provides basic bus support for all system buses on Intel platforms. Without this driver, NEXTSTEP will not boot

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
In order to better support various bus configurations, bus support was removed from the kernel and split into several bus drivers. All other bus drivers currently rely on the EISABus driver for basic services.

Known Problems

Driver Version Notes

3.31 Allows Plug and Play to be turned off. This is required for Compaq's IBM Token Ring AutoSense 16/4 board to work in their PnP-Bios equipped machines ie. the Compaq Deskpro 5100 and Prolinea 575.
3.32 Added "Force Cold Boot" switch to inspector panel. When this switch is turned on, the machine will be forced to go through a cold boot sequence every time it reboots
3.35 Significant improvements to Plug and Play support. /usr/Devices/PnPDump is provided as a useful debugging tool.
3.36 - Updated PnP ID matching routine in order to work with ESS1868 based sound cards.

An updated BETA version of this driver, version 3.39, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/IBMTokenRing.pkg.compressed

Driver Name / Installer .pkg: IBMTokenRing
Driver Type: Networking
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This is the new version of the IBM Token Ring driver which adds support for the AutoSense adapters.

Supported Products / Add-on Adapters:
IBM 25F7367 (ISA, 16/4 Mbps, 8-bit, 64K)
IBM 25F9858 (ISA, 4Mbps, 8-bit, 16K)
IBM 67X0438 (ISA, 4Mbps, 8-bit, 16K)
IBM 60G3994A? (ISA, 16/4 Mbps, 16-bit, 64K)
IBM 92G7668 (Auto, ISA, 16/4 Mbps, 16-bit, 64K)
IBM 41H8450 (Auto, ISA, 16/4 Mbps, 16-bit, 64K)

Supported Products / Systems (ie integrated into PC System):
Token Ring option for Compaq DeskPro and Prolinea series

Special Features of Driver / Driver Notes:
3COM TokenLink III 3C619B (Auto, ISA, 16/4 Mbps, 64k) (untested) is reported to work using the "IBM Auto 16/4 Token Ring ISA Adapter" personality.

Networking Driver Details

Network Type:** Token Ring
Speed*: 16 Mb/s, 4 Mb/s
Access Mode:** Memory Mapped
Buffer Size*: 64KB
Supported Connectors:** STP, UTP

Known Problems

Cannot netboot unless netinfo server is on the same ring. See also NeXTAnswer #2076_Network_Booting_for_Token_Ring_Across_Source_Routing_Bridges.rtf

Driver Version Notes

3.33 Support Auto 16/4 and add Fast Path Transmit
3.34 Survive being disconnected from the MAU, both at boot time and during operation. Fix problem with being the first node on the network.
3.36 Fix problems on a busy token ring. Symptoms include netboot flakiness/receive congestion errors. Performance improvements were also made.
3.37 Fix problem with using an MTU too large for 4Mbit rings. The driver now limits the MTU to 4472 when it automatically switches to 4Mbit/s. The MTU is also limited by the ring speed selection made on the driver's Configure panel.
3.39 Added Plug and Play driver personality to simplify adapter configuration. The adapter is now auto-detected under Configure.

NeXTSTEP 3.3 Driver: IDE

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: IDE
Driver Type: System
Driver Scope: Generic-System
Supported Components:
PC Bus / Interface Supported by Driver:** Integrated, ISA
Supported Connectors: 40-pin Header (Internal IDE)
Access Mode: PIO
Adapter Memory: N/A

General Overview notes: This driveris obsolete and had been replaced by the EIDE driver. Se NeXTansewer#1839_EIDE_Driver_Overview.rtf

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
Always use the large disk option while installing NEXTSTEP.

Known Problems

In 3.3, support was added for >504MB IDE disks, but it requires a well behaved system BIOS.

Also supports PCI IDE adapters.

NeXTSTEP 3.3 Driver: Intel 824X0 PCI Chipset Driver

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/Intel824x0.pkg.compressed

Driver Name / Installer .pkg: Intel824X0.config
Driver Type: System
Driver Scope: Generic-Chipset
Supported Components: Intel i824x0
PC Bus / Interface Supported by Driver:** Integrated
Supported Connectors:
Access Mode:
Adapter Memory:

General Overview notes: This driver fixes a flaw the the Intel 824X0 PCI chipsets. It only needs to be installed on PCI systems based on the Intel 82420 & 82430 chipsets.

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Known Problems

Write-posting was disabled in the original driver due to problems of potential data loss. The new driver will always report the PCI chip it finds. If it intends to disable write-posting, it will issue a second statement indicating that it is doing so, or that the BIOS has already done so. If no second statement is seen, then the driver believes the chip it detected is not flawed.

Driver Version Notes

3.31 Re-enable performance options for PCI that are disabled in v3.30, on those systems that can safely support them.

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
The driver has not been tested with the following adapters, but should work:
Cogent EM525 ISA (BNC/AUI)
Cogent EM525 TP ISA (RJ-45)
Cogent EM525 C ISA (BNC/RJ-45/AUI)

Networking Driver Details

Network Type:** EtherNet, Full Duplex
Speed*: 10 Mb/s
Access Mode:** PIO
Buffer Size*: 64KB
Supported Connectors:** AUI, BNC, UTP

Known Problems

· This driver has not been tested with the Cogent 525 series, but should work.
· If you have stepping 3 of the EtherExpress Pro/10, version 3.31 of the driver will complain with en0: 82595 unsupported stepping (3), but will continue to work

Driver Version Notes

3.31 Added support for EE Pro/10 ISA
3.33 Initial support for EE Pro/10+ ISA
3.35 Added Plug and Play personalities for the PRO/10 and PRO/10+.

NeXTSTEP 3.3 Driver: Intel EtherExpress 16

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/EtherExpress16.pkg.compressed

Driver Name / Installer .pkg: EtherExpress16
Driver Type: Networking
Driver Scope: Product Family
Supported Components: Intel i82586
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This driver supports the Intel Ether Express 16 adapter family.

Supported Products / Add-on Adapters:
EtherExpress16 (ISA, BNC/AUI)
EtherExpress16TP (ISA, UTP/AUI)
EtherExpress16C (ISA, BNC/UTP/AUI)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:

Networking Driver Details

Network Type:** EtherNet
Speed*: 10 Mb/s
Access Mode:** PIO
Buffer Size*: 16KB
Supported Connectors:** AUI, BNC, UTP

Known Problems

Driver Version Notes

3.31 - Fixed a bug where the adapter/driver might cause a kernel panic under heavy network load.

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

NeXTSTEP 3.3 Driver: Microsoft Sound System

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: MicrosoftSoundSystem
Driver Type: Sound
Driver Scope: Product Family
Supported Components: Analog Devices AD184
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This driver supports the Microsoft Windows Sound System. The driver should also work with any card that is 100% compatible with Microsoft Sound System.

Supported Products / Add-on Adapters:
Microsoft Sound System (ISA)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
1. The AudioTrix card made by MediaTrix uses CS4231 chipset. This card will work with this driver in 3.2 and 3.3. However in 3.2 the input gain for AudioTrix card is too high and there are recording problems.
2. NCR and Adaptec make SCSI cards with Microsoft Sound System compatible hardware on them. This driver should work with them.

Sound Driver Details

Supported Connectors: 1/8" Microphone In, 1/8" Stereo Speaker
Access Mode: DMA
Adapter Memory: N/A
Attributes: 16-bit Linear, 8-bit Linear, 8-bit Mu Law

Known Problems

· This adapter card requires one DMA channel, an IRQ level, and a port address. To change the DMA channel and/or IRQ level, run the Configure application and then restart the computer to make the changes take effect.

· Line input is not supported.

NeXTSTEP 3.3 Driver: Number Nine GXE Family

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: Number9
Driver Type: Display
Driver Scope: Product Family
Supported Components: AT&T ATT20C505 RAMDAC, Brooktree Bt484 RAMDAC, Brooktree Bt485 RAMDAC, Brooktree Bt485A RAMDAC, S3 928, S3 928P, TI TVP3020 RAMDAC
PC Bus / Interface Supported by Driver:** PCI, VL-Bus

General Overview notes: This driver is obsolete, and has been replaced by the S3GenericDisplay Driver. See NeXTanswer #1737_S3_Generic_Driver_Overview.rtf

This new Number 9 GXE graphics driver is designed to support a variety of VL-Bus and PCI graphics adapters from Number 9. These cards use the S3-928 graphics controller and support 1MB,2MB or 4MB of video frame buffer. Some versions of these adapters also support an optional additional 1MB of off screen memory, not required by NEXTSTEP. This version of the driver only supports1MB, 2MB or 4MB of VRAM.

Supported Products / Add-on Adapters:
#9GXE-VL Level 10 (VL-Bus, 1MB VRAM) - not tested, but should work
#9GXE-VL Level 11 (VL-Bus, 2MB VRAM)
#9GXE-VL Level 12 (VL-Bus, 2MB VRAM) - not tested, but should work
#9GXE-VL Level 14 (VL-Bus, 4MB VRAM) - not tested, but should work
#9GXE-VL Level 16 (VL-Bus, 4MB VRAM) - not tested, but should work
#9GXE-PCI Level 10 (PCI, 1MB VRAM) - not tested, but should work
#9GXE-PCI Level 12 (PCI, 2MB VRAM)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB VRAM, 2MB VRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
1024x768 (4MB+), 640x480 (2MB+), 800x600 (2MB+)

Driver Type: Display
Driver Scope: Product Family
Supported Components: S3 964 (Vision), TI TVP3025 RAMDAC
PC Bus / Interface Supported by Driver:** PCI, VL-Bus

General Overview notes: This graphics driver is designed to support the PCI and VL-Bus versions of the GXE64Pro Graphics adapters from Number Nine Corp. These cards are based on the S3-964 Graphics controller chipset and support 2MB or 4 MB of VRAM. This driver supports both configurations including a variety of high-resolution and high-color (32bit) modes. The high performance RAMDAC on these adapters allows support of very high resolutions including 1600x1200 with 16-bit color.

Supported Products / Add-on Adapters:
Number 9 GXE 64 Pro (PCI, 4MB VRAM)
Number 9 GXE 64 Pro (PCI, 2MB VRAM)
Number 9 GXE 64 Pro-1600 (PCI, 4MB VRAM, 200Mhz RAMDAC) - not tested, but should work
Number 9 GXE 64 Pro (VL-Bus, 4MB VRAM)
Number 9 GXE 64 Pro (VL-Bus, 2MB VRAM)
Number 9 GXE 64 Pro-1600 (VL-Bus, 4MB VRAM, 200Mhz RAMDAC) - not tested, but should work

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)

Pascal: Difference between REPEAT..UNTIL and WHILE..DO

This article has been archived and is no longer updated by Apple.
Pascal supports two forms of conditional loop: REPEAT..UNTIL and WHILE..DO.
A loop of the form

REPEAT
UNTIL <condition>

will be executed at least once, even if the condition is satisfied before the first execution.

The loop consisting of

WHILE <condition> DO

will be executed ONLY if the condition is satisfied when the loop is entered.
For further information, see pages 22 and 23 of the Pascal User Manual and Report.

TokenTalk: How To Find "Burned-In" Address

How can I find out what the "burned-in" address is for my TokenTalk Card?

This article has been archived and is no longer updated by Apple.
Although you can find out what the "burned-in" address is using the MacDFT Config CDEV, there are times when you don't have this handy.

When holding the card, port to the right and the chip set facing you, look for the ROM card (the card on the card). Now look for the serial number of the card. It is printed on a label two chips to the left of the ROM card on the second row from the top. It is proceeded with S/N.

Once you have found this decimal number, convert it to hex. Now add the result (in hex) to 5000E0000000. This will be your address.

For example:

If your card's serial number is: 1969 (with a bunch of leading zeros)

1969 base 10 = 7B1 hex

5000E0000000 + 7B1 = 5000E00007B1 <= your address.

Driver Name / Installer .pkg: PCIC
Driver Type: System
Driver Scope: Generic-Chipset
Supported Components: Intel i82365
PC Bus / Interface Supported by Driver:** PCMCIA
Supported Connectors:
Access Mode:
Adapter Memory:

General Overview notes: This driver supports the Intel 82365 chip set, which is used to provide PCMCIA socket support.

Supported Products / Add-on Adapters:
SwapBox Classic MMCD-D - Not test by SQA, might work.

Supported Products / Systems (ie integrated into PC System):
NEC Versa E Series
NEC Versa V Series
NEC Versa 4000
Compaq LTE Elite
IBM Thinkpad 755CX
Adaptec CardPark

Special Features of Driver / Driver Notes:
This driver is necessary when using the Intel 82365 PCMCIA chipset with PCMCIA devices. See also NeXTanswer 1801_PCMCIABus

Known Problems

Hot insertion and removal of PCMCIA devices is not supported.

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.32) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.31 Fixes a bug which could result in inconsistent adaptor initialization.
3.32 Adds support for PCIC compatible PCI-PCMCIA Bus Bridges

This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: S3
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: AT&T ATT20C491 RAMDAC, AT&T ATT20C505 RAMDAC, Brooktree Bt484 RAMDAC, Brooktree Bt485 RAMDAC, Brooktree Bt485A RAMDAC, S3 801, S3 805, S3 911
PC Bus / Interface Supported by Driver:** Integrated, VL-Bus

General Overview notes: This driver is obsolete and has been replaced by the S3GenericDisplay Driver. See NeXTanswer #1737_S3_Generic_Driver_Overview.rtf

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):
IBM PS/ValuePoint
Hewlett-Packard Vectra XM
DECpc 466d2 MTE

Special Features of Driver / Driver Notes:

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 2MB VRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
1024x768 (4MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 1280x1024 (4MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1280x1024 (2MB+)

NeXTSTEP 3.3 Driver: SCSI Tape

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/SCSITape.pkg.compressed

Driver Name / Installer .pkg: SCSITape
Driver Type: System
Driver Scope: Generic
Supported Components:
PC Bus / Interface Supported by Driver:**
Supported Connectors:
Access Mode:
Adapter Memory:

General Overview notes: This is a SCSI Tape peripheral driver. It supports most SCSI tape drives that use the generic SCSI command set for Tape Devices. A SCSI Host Adapter and associated NEXTSTEP driver are required in order to use this driver

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
For release NS 4.0, SCSITape is being moved from the Other category to the SCSI category.

Sun DAT drives cause other tape drives with higher SCSI ID's to not be registered. This is a hardware problem. The workaround is to place non-Sun tape drives at a lower SCSI ID than the Sun DAT drive.

Known Problems

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.31) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.31 Corrects a problem restoring data from tapes. This problem was encountered when using /dev/rst# device nodes, where # is a number. This problem only effects tape reads, so tapes written using this driver should be correct.

Driver Name / Installer .pkg: SMC16
Driver Type: Networking
Driver Scope: Product Family
Supported Components: SMC SMC83C690
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This driver supports the SMC EtherCard Plus Elite16 Ethernet Adapter

Supported Products / Add-on Adapters:
SMC EtherCard Plus Elite16 Ethernet Adapter

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:

Apple Coax/Twinax Card: Rev B Fixes MacDFT & Video Problems

What does the "new" Apple Coax/Twinax card revision do? Who needs it?

This article has been archived and is no longer updated by Apple.
The new Apple Coax/Twinax card offers no new functionality, but it does resolve a somewhat rare incompatibility problem with the Macintosh Display Card 8*24 and Macintosh Display Card 8*24 GC. The only difference between this "new" card and the "old" one is that the inductor/ferrite bead replaces a jumper wire, and the masking on the board says that the board is revision "B."

You should consider upgrading to the new cards if you have the following problem:

MacDFT hangs on boot when the initial "splash screen" appears. MacDFT hangs before the Window Manager completes drawing the window frame, or shortly after the frame draw and the content region goes black. This problem happens often on systems with 8*24 style video and Coax/Twinax cards. It is also more likely to happen on a Macintosh IIci, Macintosh IIcx, or Macintosh IIfx than on a Macintosh II or Macintosh IIx.

But a similar problem has a different solution: Some NuBus conflicts happen with the Portrait or Workstation display cards and the Apple Coax/Twinax card. The error shows up when launching MacDFT. At launch, the Macintosh bombs and gives a bus error (if the system has MacsBug installed) or displays a system error of ID=28. Use A/ROSE v1.1.2 to fix this problem.

NeXTSTEP 3.3 Driver: Sound Blaster 16

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/SoundBlaster16.pkg.compressed
An updated BETA version of this driver, version 3.34, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/SoundBlaster16.pkg.compressed

Driver Name / Installer .pkg: SoundBlaster16
Driver Type: Sound
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This driver support most SoundBlaster 16 and 100% compatible sound cards.

Supported Products / Add-on Adapters:
Sound Blaster 16 Basic (ISA)
Sound Blaster 16 Value (ISA)
Sound Blaster 16 AWE (ISA)
Sound Blaster 16 SCSI-II (ISA)
Sound Blaster 16 Value PnP (ISA)
Sound Blaster AWE 64 Value (ISA)
Sound Blaster AWE 64 Gold (ISA)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
Only simple playback and recording are supported. Wave table related hardware is unsupported.

The SCSI interface on the Sound Blaster 16 SCSI-II has been reported to work with our Adaptec 6x60 driver, though is not a supported configuration.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Sound Driver Details

Supported Connectors: 1/8" Microphone In, 1/8" Stereo Line-In, 1/8" Stereo Line-Out, 1/8" Stereo Speaker , CD-ROM Stereo Line-In
Access Mode: DMA
Adapter Memory:
Attributes: 16-bit Linear, 8-bit Linear

Known Problems

In order to configure resources (like IRQ, DMA, port addresses) correctly, make sure that the system BIOS knows about the resources used by this and other ISA adapters.

Use the PnP personality for SB16 PnP boards and enable support for Plug and Play in the EISABus driver (if you are using the driver from NextAnswers).

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.34) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.33: Added support for Plug and Play cards.
3.34: Updated the PnP personality tables. Improved reliability of sound playback and recording.

This article has been archived and is no longer updated by Apple.

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: SoundBlaster8
Driver Type: Sound
Driver Scope: Product Family
Supported Components: Creative Labs
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This driver is intended to support all 8-bit Sound Blaster cards and compatible. Motherboards implementations should work as well.

Supported Products / Add-on Adapters:
Sound Blaster Basic ISA)
Sound Blaster Pro (ISA)
Sound Blaster Delux (ISA)
Sound Blaster Value (ISA)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
Limitations: Mixing is not supported and there is no sample rate conversion. This driver will not work with NEXTSTEP 3.2. Only the Sound Blaster Pro card has an on-board mixer and supports output volume control via software. For others there is typically a potentiometer in the adapter.

There are many kinds of Sound Blaster 8-bit cards and they have varying features.

NeXTSTEP 3.3 Driver: STB Pegasus DisplayN

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/Pegasus_Display.pkg.compressed

Driver Name / Installer .pkg: PegasusDisplayDriver
Driver Type: Display
Driver Scope: Product Family
Supported Components: AT&T ATT20C505 RAMDAC, Brooktree Bt485A RAMDAC, S3 928
PC Bus / Interface Supported by Driver:** VL-Bus

General Overview notes: The STB Pegasus-VL graphics driver is designed to support the VL-Bus version of the Pegasus graphics adapter from STB. This card uses the S3-928 graphics controller and supports 1MB,2MB or 4MB of video frame buffer. This version of the driver only supports1MB, 2MB or 4MB of VRAM.

Supported Products / Add-on Adapters:
STB Pegasus (VL-Bus, 4MB VRAM)
STB Pegasus (VL-Bus, 2MB VRAM)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB VRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
1024x768 (4MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 1152X819 (4MB+), 1280x1024 (4MB+), 1600x1200 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1152X819 (1MB+), 1280x1024 (2MB+), 800x600 (1MB+)

Known Problems

Version 3.31 of this driver is named differently than version 3.30 which shipped on the NEXTSTEP3.3 CD-ROM. Installing the newer version will leave both drivers co-resident, so both versions will be visible in Configure.app. Remove any instances of the older version and replace them with instances of the newer driver.

Driver Version Notes

3.30 - Shipped with NS3.3 - based on interpreted IOVP code
3.31 - Total re-write in ObjC - 8 bit color modes added

1024x768 (1MB+), 1120x832 (1MB+), 1280x1024 (2MB+), 800x600 (1MB+)

Known Problems

NeXT SQA has experienced some display problems with the ATI Mach32 VL-Bus adapter on machines using the OPTi chip-set. One of the problems is the machine will hang in any of the 8-bit greyscale display modes. However, machines without this chip-set behave normally.

NeXT SQA has witnessed some video noise in 800x600 display modes for adapters with the 68003 Mach32 chip.

NeXTSTEP 3.3 Driver: Cirrus Logic GD5434

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/CL_GD5434.pkg.compressed

Driver Name / Installer .pkg: CirrusLogicGD5434DisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: Cirrus Logic GD5434
PC Bus / Interface Supported by Driver:** Integrated, PCI, VL-Bus

General Overview notes: This driver is intended to support on-board implementations of GD5434 as well as add-on adapters.

Supported Products / Add-on Adapters:
Diamond SpeedStar 64 (PCI)
Orchid Kelvin 64 (with GD5434)

Supported Products / Systems (ie integrated into PC System):
Elonex WS4100
Intel Premier (with integrated GD5434)
HP Vectra XM Series3 (not tested but reported to work)

Special Features of Driver / Driver Notes:
Because this chip has an integrated RAMDAC with only an 8 bit palette, Preferences's Brightness slider (and hardware gamma correction in general) doesn't work for any non-8 bit modes. Also the 32-bit colors look dark. There is no fix for these problems.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1280x1024 (2MB+), 800x600 (1MB+)

Known Problems

Cirrus Logic GD5430 is not supported but is reported to work with this driver.

Driver Version Notes

3.31 Added support for PCI cards and 8 bit color

A/UX 2.0.1: Fixes "ls -F" Bug

In A/UX 2.0, ls -F should display the current directory's content appending *, /, @, to denote executable, directory, and symbolic link.

I linked a directory to another symbolic link, but when I typed in ls -F, I see xxx/ rather than xxx@. Although when I typed in ls -l, I can see the symbolic linked directory is linked -> to another directory.

This is a bug in A/UX 2.0 that has been fixed in A/UX 2.0.1.

Debugging EOF 1.x under NeXTSTEP 3.2 and 3.3

This document discusses debugging for Apple's Enterprise Objects Framework, versions 1.0 and 1.1, under versions 3.2 and 3.3 of the NeXTSTEP operating system. The information contained in this document may not apply to any other version of EOF or to any other Apple product.
This article has been archived and is no longer updated by Apple.

Questions

Q: Occasionally my EOF 1.x for NeXTSTEP application exits and produces "Unknown error 100003 in NXReportError". This message is not very informative and makes debugging the application difficult. Is there a way to get more information than this?

Q: From gdb, how can I get information about private Foundation and EOF objects such as the concrete classes in a class cluster?

Q: I am trying to send messages to my adaptor from gdb while debugging my EOF application but gdb tells me that the adaptor objects do not respond to any selectors. What's the problem?

Q: How do I get a listing of the SQL code that is sent to the server?

Q: I am trying to compile my EOF application to run with MallocDebug and I get the following errors:

```
ld: multiple definitions of symbol __NXMallocCheck
/usr/lib/libMallocDebug.a definition of __NXMallocCheck in section
(__TEXT,__text)
/lib/libsys_s.a(malloc.o) definition of absolute __NXMallocCheck
(value 0x5002432)
ld: multiple definitions of symbol __NXDefaultMallocZone
/usr/lib/libMallocDebug.a definition of __NXDefaultMallocZone in
section (__TEXT,__text)
/lib/libsys_s.a(malloc.o) definition of absolute
__NXDefaultMallocZone (value 0x5002444)
```

What is happening?

Q: When my application raises an exception, I can't get a backtrace even if I am running it from within gdb. This makes debugging difficult. How can I get a backtrace when it raises?

Answers

Here are some useful EOF debugging tips to address these questions.

A: You can implement a top-level error handler that catches all unknown errors, and figure out what the error was and print a more useful message. Here is an example of some code that does this. First, call this someplace early in the app's execution such as **appDidInit:** or the **awakeFromNib** method for one of your top-level objects:

```
NXSetTopLevelErrorHandler(MyTopLevelErrorHandler);
```

"MyTopLevelErrorHandler" must be a function defined with this prototype:

```
void MyTopLevelErrorHandler(NXHandler *errorState);
```

Here is an example of an implementation that simply logs a message to the console with NSLog(). You can implement your own mechanism for presenting the error message, including raising an alert panel, logging a message with NSLog() or printf(), or any combination of these.

```
void MyTopLevelErrorHandler(NXHandler *errorState)
{
if (errorState->code >= NSExceptionBase &&
errorState->code <= NSLastException) {
NSException *exception = (id) errorState->data1;

NSLog(@"%@: %@\\n", [exception exceptionName], [exception exceptionReason]);
}
}
```

A: gdb's "print-object" command (abbreviated "po") sends a **description** message to an object and prints the results. Most Foundation and EOF objects implement **description** in a meaningful way and will give you information about their contents. You can implement **description** on your own custom objects to look at their contents from gdb. The syntax for the command is:

```
(gdb) po anObject
```

A: The NSBundle class has a class method called **stripAfterLoading:** that allows you to control whether or not symbols are stripped from bundles then they are loaded. Please see NeXTanswer 1720_Debugging_code_loaded_by_NSBundle for more information.

A: There are two ways to see the SQL code that is sent to the server. One way is to turn on debugging output in the adaptor. If you have an outlet to an EOController instance, you can do this with the following:

```
[[[(EODatabaseDataSource *)[controller dataSource] databaseChannel] adaptorChannel] setDebugEnabled:YES];
```

The typecast is necessary because the data source for an EOController does not have to be an EODatabaseDataSource instance; if you know that it is, you can typecast it in this manner to get rid of the compiler warning.

Another way to see the SQL code is to become the delegate for the EOAdaptorChannel and respond to the **adaptorChannel:willEvaluateExpression:** method. To become the delegate, you can do the following at awakeFromNib time (again assuming that you have an outlet to an EOController instance):

```
[[[(EODatabaseDataSource *)[mainController dataSource] databaseChannel] adaptorChannel] setDelegate:self];
```

Then that object can implement the EOAdaptorChannel's delegate method like this. In this example, the SQL code is logged with NSLog(). You can implement your own mechanism for displaying the SQL code including adding it to an on-screen Text objects, logging it with NSLog() or printf(), or any combination of these. Note that it is important to return EODelegateApproves from this method in order for the code to be sent to the server and work correctly.

```
- (EODelegateResponse)adaptorChannel:channel willEvaluateExpression:(NSMutableString *)anExpression
```

```
{
NSLog(@"%@\\n",anExpression);
return EODelegateApproves;
}
```

A: To resolve undefined symbols when using MallocDebug, you need to do the following:

1) remove the -all_load flag from OTHER_LDFLAGS in your Makefile.preamble.

```
OTHER_LDFLAGS =
```

2) hardlink your adaptor. For example, this will be the new entry in your Makefile.preamble if you use the Sybase adaptor:

```
# Additional relocatables to be linked in at this level
OTHER_OFILES = /NextLibrary/Adaptors/Sybase.dbadaptor/Sybase
```

3) link with MallocDebug:

```
# Additional libs to link apps against ('app' target)
OTHER_LIBS = -lMallocDebug
```

A: If you break on [NSException raise], you will be able to generate a backtrace, since this routine is called whenever an exception is raised. You can configure gdb so that it will always break on this routine by adding this line:

```
b [NSException raise]
```

to the .gdbinit file in your project directory. You can't add it to the .gdbinit in your home directory, since that is loaded before the symbols for Foundation are loaded -- you need to put it in your project directory.

Note that after you have broken on this method, it is often useful to print the reason for the exception. You can do this on Intel and Motorola platforms with the following command from gdb:

```
(gdb) po [*((id *)($fp + 8)) exceptionReason]
```

You can define a new command called "reason" to do this for you like this:

```
(gdb) define reason
po [*((id *)($fp + 8)) exceptionReason]
end
(gdb) document reason
Print the reason for an NSException.
When a program is inside of the method -[NSException raise], this
command prints out a textual reason for the exception.
end
```

You CAN add these commands to the .gdbinit file in your home directory so that they will always be available whenever you run gdb.

A/UX: AppleTalk Printing Problem (8/94)

When I try printing from A/UX to a LaserWriter IINTX connected to an AppleShare Print Server, I get a message that says that the Laser Prep version is not correct.

This article has been archived and is no longer updated by Apple.
The message you are getting is because the LaserWriter driver and its Laser Prep in the A/UX /mac/sys/System Folder are different from the one in the AppleShare Printer Server in the AppleTalk network. Use the same version of LaserWriter driver and Laser Prep files and/or PrintMonitor as the ones in the Printer Server.

Availability Information

An updated release version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/DPTSCSI.pkg.compressed

Driver Name / Installer .pkg: DPTSCSIDriver
Driver Type: SCSI
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver:** EISA, Integrated, ISA, PCI

General Overview notes: The DPT SCSI driver update is designed to support the 2000 and 3000 series of SCSI adapters from DPT. This driver does not support the DPT 2011 ISA Adapter. The DPT 32xx series SmartRAID SCSI adapters include RAID and Cache capability, and support from 1 to 3 SCSI channels. This driver replaces the NEXTSTEP 3.3 DPT 2000 Adapter driver.

Supported Products / Add-on Adapters:
Model# Bus Description
PM2021/90 ISA SCSI adapter
PM2021/95 ISA SCSI adapter
PM2022/90 EISA SCSI adapter

Availability Information

An updated release version of this driver, version 3.31, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/EIDE.pkg.compressed
An updated BETA version of this driver, version 3.37, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/EIDE.pkg.compressed

Driver Name / Installer .pkg: EIDE
Driver Type: System
Driver Scope: Generic-System
Supported Components: PC Tech RZ1000
PC Bus / Interface Supported by Driver:** Integrated, ISA, PCI
Supported Connectors: 40-pin Header (Internal IDE)
Access Mode: PIO
Adapter Memory:

General Overview notes: This drivers supports IDE disks and IDE ATAPI rev. 1.2 compliant CD-ROMs. It supports primary and secondary IDE controllers with up to 2 drives per controller. Please refer to 1933_EIDE_and_ATAPI_CDROM_Support_in_NEXTSTEP_3.3.rtf for more information on configuring your EIDE drives for NEXTSTEP.

This driver replaces the IDE driver distributed on the NEXTSTEP 3.3 CD.

Supported Products / Add-on Adapters:
The following ATAPI CD-ROM drives are supported:
Chinon CD-ROM CDS-525 (2X), firmware rev. W09
Matsushita CD-ROM CR-571 (2X), firmware rev. 1.0e -- Panasonic
Mitsumi CD-ROM 1B (4X), firmware rev. B02 -- model FX400
Sony CD-ROM CDU55E (2X), firmware rev. 1.0u
Sony CD-ROM CDU76E-S (4X), firmware rev. 1.0c
Toshiba CD-ROM XM-5302TA (4X), firmware rev. 0305

The beta driver adds support for the following ATAPI CD-ROM drives:
Philips CM207, firmware rev 1.10 (??) -- reported to work
SONY CD-ROM CDU76E-Q, firmware rev 1.0c (4X)
SONY CD-ROM CDU55D, firmware rev 1.0v (2X)
SONY CD-ROM CDU77E, firmware rev 1.0e (4X)
TORiSAN CD-ROM CDR-S1, firmware rev 1.70 (4X) -- SANYO
Chinon CD-ROM CDS-545, firmware rev ERc A1.0 (4X)
GoldStar CD-ROM GCD-R540, firmware rev 1.17 (4X)
GoldStar CD-ROM GCD-540C, firmware rev 1.01 (4X)
SANYO CRD-254P, firmware rev 1.02 (4X)
MATSHITA CD-ROM CR-574, firmware rev 1.06 (4X) -- Panasonic
Pioneer CD-ROM DR-UA124X, firmware rev 1.02 (4X) -- force detection
MITSUMI CD-ROM !B, firmware rev K02 (4X) -- DRM FX400B
TEAC CD-55E, firmware rev ?? (4X) -- Thinkpad 760CD
ATAPI CD-ROM SPEED-6X, firmware rev 6.2D (6X) -- ACER 665A
VERTOS 600ESD CD-ROM X6-IDE, firmware rev 1.20 (6X)
TEAC CD-56E, firmware rev 1.0D (6X)
MATSHITA UJDCD4700, firmware rev 1.11 (??)
TEAC CD-58E, firmware rev 1.1B (8X)
Toshiba CD-ROM XM-5602B, firmware rev 1426 (8X)
Sony CD-ROM CDU311, firmware rev 3.0i (8X)
EPSON CMD-2240 SPEED-6X, firmware rev R100 -- reported to work
Hitachi CDR-7730, firmware 1.1a (4X)
TEAC CD-524E, firmware 4.0D (24X)

Supported Products / Systems (ie integrated into PC System):
Other ATAPI 1.2 compliant CD-ROM drives should work with NEXTSTEP even if they are not in the supported list. If a CD-ROM drive does not work with NEXTSTEP (or even if it does) we would like to know about it. Please send an email message to nextanswers-request@next.com including the model number of the CD-ROM drive and also whether this drive is connected as a master or a slave.

Special Features of Driver / Driver Notes:

NeXT's EIDE driver is not affected by the RZ1000 hardware bug.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Known Problems

These devices are not supported.
1. NEC CDR-260 (2X)
2. NEC CDR-273

To get the Pioneer DR-UA124X 1.02 CD-ROM to work you must force detection. You can do this by going in Expert mode and adding the key "Slave"="ATAPI" (or "Master" as the case may be) to the table.

Driver versions 3.33 and below can cause certain systems to hang under very heavy load.

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.34) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.33: This version adds support for several new ATAPI CD-ROM drives and fixes some bugs.
3.34: Fixed a bug which could cause machines to hang under very heavy load.
3.36: Added device overrides and modified the inspector. The new overrides are documented in the driver help.
3.37: Improved ATAPI support. Added support for Intel PIIX PCI IDE controllers. Added Bus Master support. Revised the driver Inspector.

EOF 1.x and Oracle NOWAIT Locks

This document discusses a feature commonly requested by users of certain versions of Apple's Enterprise Objects Framework.
This article has been archived and is no longer updated by Apple.

Question

Q: EOF provides the ability to use pessimistic locks by sending EOUpdateWithPessimisticLocking to EODatabaseContext's setUpdateStrategy: method. However if client A has the pessimistic lock and client B tries to access the locked row(s), client B blocks until client A releases the lock.

Oracle 7 supports "NOWAIT" locks which allows client B in this scenario to return immediately after failing to get the lock, allowing it to present an error message or otherwise handle the situation. Is this supported in EOF?

Answer

A: Although this feature is not explicitly supported in the EOF 1.1 Oracle7 adaptor, it is very easy to add. The only difference between getting a pessimistic lock and a NOWAIT pessimistic lock is the NOWAIT keyword appended to the end of the SELECT clause that gets the lock. This functionality can be added in an EOAdaptorChannel delegate with the following code. (This object needs to be the delegate of both the EOAdaptorChannel and EOAdaptor; this can be set up in awakeFromNib).

```
#import <eoaccess/eoaccess.h>

@interface ExampleNOWAITDelegate
{
BOOL locking;
}

@end

@implementation ExampleNOWAITDelegate

- (EODelegateResponse)adaptorChannel:channel
willSelectAttributes:(NSMutableArray *)attributes
describedByQualifier:(EOQualifier *)qualifier
fetchOrder:(NSMutableArray *)fetchOrder
lock:(BOOL)flag
{
locking = flag;
return EODelegateApproves;
}

- (EODelegateResponse)adaptorChannel:channel
willEvaluateExpression:(NSMutableString *)expression
{
if (locking && [self useNOWAIT])
[expression appendString:@" NOWAIT"];

return EODelegateApproves;
}

- (BOOL)adaptor:(EOAdaptor *)adaptor
willReportError:(NSString *)error
```

```
{
/*
* error is the error message provided by the adaptor; if it begins
* with "ORA-00054:", the resources that we want to lock are busy.
* Here we just call NSLog(), but ultimately we should provide an
* alert panel for the user or otherwise handle this.
*/
if([error hasPrefix:@"ORA-00054:"]) {
NSLog(@"NOWAIT resources busy!\\n"); // Should act accordingly
return NO;
}

return YES;
}

- (void)adaptorChannel:channel
didEvaluateExpression:(NSString *)expression
{
locking = NO;
}
@end
```

System 6.0.5 & 6.0.7: Helvetica Narrow Fonts (11/94)

System 6.0.7 Installer has a FONT problem if I:

1) Install the FONTs from the LaserWriter IINT into the System.

2) Create a MacWrite document using Helvetica and N Helvetica Narrow.

3) Update the System software with Easy INSTALL. It doesn't matter if I'm updating from 6.0.5 to 6.0.5, 6.0.5 to 6.0.7 or 6.0.7 to 6.0.7.

4) Look at the FONTs in the MacWrite menu. I still have N Helvetica Narrow, but the text that should be N Helvetica Narrow is Geneva.

5) Look in the System file FONT list with ResEdit. The N Helvetica Narrow family still exists, but the individual FONTs normally listed under the family heading have disappeared.

This problem appears on a Macintosh IIsi, Macintosh SE or Macintosh Classic running System Software 6.0.5 or 6.0.7 (Swedish or U.S. versions).

This article has been archived and is no longer updated by Apple.
Reinstalling the Narrow FONTs fixes this problem. After reinstalling, all the other FONTs should be all right, too.

HP 2P LaserPrinter: Connecting to a Macintosh

Is there any way to connect a Macintosh to an HP 2P LaserPrinter? I have unsuccessfully tried using the Orange Micro Grappler LX. The Grappler LX does work, however, with the HP LaserJet Plus.

This article has been archived and is no longer updated by Apple.

We contacted Orange Micro and found that the HP 2P and Macintosh computers using a 68020, 68030, or 68040 can connect with a Grappler LX. Macintoshes using a 68000 must use the Orange Micro Grappler LS.

Orange Micro also states that the HP printer must have a minimum of 1MB of RAM to function properly with their equipment.

MacX: How To Specify Available Window Fonts

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

I want to use the Fonts selection feature in MacX to customize the font selection in DECterm windows.

How do I use this menu item?

This article has been archived and is no longer updated by Apple.
The "F" item in the MacX "Edit" menu, or Command-F, brings up the Font Director dialog box. Font Director lets you see a sample of the typeface without having to run font clients or type commands with long and cryptic font names. Font Director also lets you sort fonts in various ways, assign aliases to font names, and compile fonts from Bitmap Distribution Format (BDF) files.

To use this command, tell the DECterm client which font to use in the window. Specify a font in the remote command to invoke the X client (DECterm in your case). This is similar to the "-fn" option when you invoke "xterm" in UNIX.

The command to invoke DECterm is CREATE/TERMINAL. To specify which font to be used in the window, use the /WINDOW_ATTRIBUTES=(keyword [,...]) qualifier. The keyword is FONT for this case. Example:

```
create/terminal/window=(rows=24,columns=75,font=timR24)/
application_keypad/insert/line_editing/detached
```

The above command creates a DECterm window using X font alias timR24. Note that you can abbreviate the VMS qualifier so the command string doesn't exceed the 255 character limit.

NeXTSTEP 3.x Foundation Version Dependencies

In preparation for the move to OpenStep, many of NeXT's software products are being based on the Foundation Kit. However, the Foundation Kit itself is still evolving as bug fixes and improvements are being made to it. This brings up the question of which Foundation shipped with which software, and dependencies of your own software on the various Foundation Kits available.

This article has been archived and is no longer updated by Apple.

What Shipped With What

The following is a short synopsis of which Foundation was shipped with EOF 1.0, EOF 1.1, and NEXTSTEP 3.3 and what this means to users and developers:

The 'short' story is:
·1.1 EOF applications are backward binary compatible with EOF V1.0 applications (i.e., any 1.0 EOF application will execute under EOF V1.1)
· The reverse is not true: EOF V1.1 applications will not work under EOf V1.0
· EOF V1.0 does *not* overwrite Foundation installed by NEXTSTEP 3.3 Intel and 68k
· NEXTSTEP 3.2 does not contain Foundation
· EOF V1.0 does install Foundation on all NEXTSTEP 3.2 platform
· EOF V1.1 overwrites Foundation installed by NEXTSTEP 3.3 Intel and 68k
· If customers have EOF V1.1 installed on their NEXTSTEP 3.3 system, they will not be able to develop applications with 3.3 Foundation
· 3.3 Foundation applications keep running after customers install EOF V1.1

These are the different versions of Foundation that have been shipped:
· Foundation A shipped with EOF V1.0
· Foundation A' (same source as A but different binary) shipped with 3.3 Intel and Motorola, 3.3RISC, and 3.3Developer
· Foundation B shipped with EOF V1.1, and will ship with PDO 3.0

Note that that the Foundation dependencies are in effect whether or not you use EOF or PDO. If you use Foundation anywhere in your code, you will need to worry about these dependencies.

Foundation Based Distributed Objects

If you are writing applications using Foundation-based DO, make sure that both the client and the server are using the same version of Foundation. Your applications will not work otherwise.

NeXTSTEP 3.3 Driver: HP Vectra XU Display

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.30, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/HPXU_Display.pkg.compressed

Driver Name / Installer .pkg:
Driver Type: Display
Driver Scope: Specific Product
Supported Components: AT&T ATT21C498 RAMDAC, S3 864 (Vision), STG 170x
PC Bus / Interface Supported by Driver:** Integrated

General Overview notes: This graphics driver is designed to support the on-board graphics controller of the Hewlett Packard Vectra XU series. The on-board graphics controller is based on the S3-864 chipset and supports 2MB of DRAM.

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):
HP Vectra/XU S3/864 on-board video

Special Features of Driver / Driver Notes:

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB DRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1280x1024 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.30) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

NeXTSTEP 3.3 NetInfo Clone Bug

Disclaimer

This document pertains to the NeXTSTEP 3.3 operating system. NeXTSTEP 3.3 is no longer a supported Apple product. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software.
This article has been archived and is no longer updated by Apple.

Question

Why can **SimpleNetworkStarter** create a NetInfo clone on Intel hardware, but using **NetInfoManager** doesn't work in NEXTSTEP 3.3 for Intel?

Answer

When you use the "Manage Hierarchy" menu in **NetInfoManager** to make a clone, it actually invokes **nidomain -c**. When **nidomain -c** invokes **netinfod -c**, a byte ordering problem occurs: the byte order of the master's address is reversed.

For example, you clone the **/ts** domain on the local host **rhino**. The master of **/ts** is running on **sabre**, with a tag of **network**. Assuming you want to your clone domain to have the same tag as the master, uniform tagging, the **nidomain** command that gets invoked is:

```
nidomain -c network sabre/network
```

nidomain will translate **sabre** to the IP address **192.42.172.66**, and will invoke **netinfod** as:

```
/usr/etc/netinfod -c sabre 66.172.42.192 network network
```

The arguments after the **-c** are the master's host's name, the master's host's IP address, the master's tag, and the new clone's tag. The bug is the reversed byte ordering of the IP address after "sabre".

Solution

-Copying the Database

Login as root and launch **Terminal**. If you just tried using **NetInfoManager**'s Manage Hierarchy menu to create the clone, kill (**kill -TERM**) the **netinfod -c** process.

```
rhino] ps -aux | grep netinfod
root 3938 1.6 0.6 1.66M 200K p3 S 0:00 grep netinfod
root 219 0.0 1.3 1.64M 424K ? SW 0:12 /usr/etc/netinfod local
root 220 0.0 0.8 2.22M 264K ? SW 0:03 /usr/etc/netinfod -c sabre 66

rhino] kill -TERM 220
```

Now change directory to **/etc/netinfo**, remove **network.nidb** (or **network.mov**, or **network.tmp**) if it exists and run **netinfod -c** by hand, giving the IP address of the master's host in the correct order. The arguments after the **-c** are the master's host's name, the

master's host's IP address, the master's tag, and the new clone's tag.

```
rhino]/usr/etc/netinfod -c sabre 192.42.172.66 network network &
```

-Adding the Serves Property

Next, add a serves property of **./network** to the **/machines/rhino** entry of the NetInfo domain you are cloning.

```
rhino] niutil -appendprop -t saber/network /machines/rhino serves ./network
```

Do the following until you get **./network** on the **serves:** line in the output,

```
rhino] niutil -read -t localhost/network /machines/rhino
```

Once the database is updated, reboot the clone machine because the new **netinfod**, the one started by hand with **/usr/etc/netinfod -c**, isn't a child of **nibindd**.

Reminder: If you have a three level or greater NetInfo hierarchy, you may need to modify the child as well as the parent domains. See the **System Administration Guide**, **Chapter 10:** Configuring a Large Network, located online in **/NextLibrary/Documentation/NextAdmin**.

IBM Token Ring Bridge: Filter Programs

I have a customer who needs to set up an IBM Source Routing Bridge to filter AppleTalk in order to allow us to run an Internet Router in parallel with it. IBM supplied them with some sample programs, but these sample programs only show how to filter ranges of Token Ring addresses. This would be fine if the only Token Ring cards running AppleTalk were Apple's cards, but this is not the case. Do you know of anyone that has written an AppleTalk protocol filter for this bridge that might share this code with my account? What types of filters are supported by the Token Ring Bridge program?

This article has been archived and is no longer updated by Apple.
We are not aware of anyone having an IBM Token Ring Bridge filter program for AppleTalk. The Token Ring Bridge program supports three types of filters:

1. Link Limiting Filter: to be used for remote bridge, such as two half bridges connected by a T1 line.
2. NetBIOS Filter: to accept or discard only NetBIOS protocol.
3. Address Filter: to accept or discard a range of Token Ring address.

According to the IBM Token Bridge Program 2.1 User's Guide, you can have up to 10 filters in the FILTER.BAT file. Thus, you can add one or more address filters in this file to filter out the token ring addresses of the other non-Apple token ring cards. Otherwise, you have the option to write your own AppleTalk filter using DOS Macro Assembler language.

OPENSTEP Boot and Driver Disk Images

These floppy images have been created as a convenience for those who may have a damaged install floppy, or who need to get crucial drivers onto an OPENSTEP floppy but don't have a running OPENSTEP machine.

If you have a damaged installation floppy, the only way to create a new one, even under OPENSTEP, is to make a copy of another one. The instructions for creating floppies from images under OPENSTEP are in the next section.

If you have a machine configuration which requires for installation a certain driver (usually a SCSI adapter driver) which is not provided on the installation driver floppy, and you don't already have a running OPENSTEP system, you can create a driver floppy under another system. If you have DOS running on your PC, you can download the proper driver floppy image and create an OPENSTEP disk under DOS using the rawrite program, available at:

http://ftp.debian.org/debian/tools/rawrite2.zip

This document only discusses floppy images for the OPENSTEP operating system, versions 4.0 and later. If you need NeXTSTEP version 3.3 or earlier floppy images, see the following Tech Info Library article:

Article 72667: "**NeXTSTEP Boot And Driver Disk Images**"

This article has been archived and is no longer updated by Apple.

Creating OPENSTEP Floppies From Images Under OPENSTEP

1. Make sure you are logged in as root.

2. Download the floppy image and decompress it from the Workspace via the File->Uncompress menu item. Make sure you are logged in as root.

3. Insert a blank 1.44 megabyte 3.5" HD floppy disk into the floppy drive.

4. In the Workspace, choose the command Check For Disks from the Disk menu. Initialize the disk as an OPENSTEP filesystem. When the disk is done initializing, select Eject from the disk menu, but leave the floppy in the drive.

5. If you have placed the image in `/tmp`, type this command to copy the boot floppy image to the new disk.

```
# dd if=/tmp/Floppy_Image of=/dev/rfd0b
```

6. After a few minutes, the duplication will be complete. Type this command:

```
# disk -e /dev/rfd0b
```

7. Physically eject the disk from the drive. It is ready to use.

Creating OPENSTEP Floppies Under Windows NT

1. Download the rawrite 2 utility from:

http://ftp.debian.org/debian/tools/rawrite2.zip

2. Download the floppy image that you need to your DOS system. Remember that DOS will not support the original OPENSTEP filename.

3. Prepare a floppy by formatting it for DOS.

4. Run rawrite. It will ask you for the source file (the floppy image) and the destination drive.

5. When rawrite has completed, the floppy is ready to be used under OPENSTEP.

NeXTSTEP 3.3 Driver: DECChip 21140 Network

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/DECChip21140.pkg.compressed
An updated BETA version of this driver, version 3.35, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/DECChip21140Net.pkg.compressed

Driver Name / Installer .pkg: DECchip21140NetworkDriver
Driver Type: Networking
Driver Scope: Specific Product
Supported Components: DEC DECchip21140
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver supports 10Mb/s and 100Mb/sec adapters based on DECchip21140.

Supported Products / Add-on Adapters:
Cogent EM100 Fast Ethernet Adapter
Cogent EM110 Fast Ethernet 10/100 Adapter
Cogent EM110-T4 Fast Ethernet 10/100/BNC Adapter
DEC DE500 Fast EtherWORKS PCI 10/100
SMC 9332 Fast Ethernet 10/100 Adapter
SMC EtherPower 10/100 B Fast Ethernet Network Adapter (9332BDT)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Networking Driver Details

Network Type:** 100 Base T4, 100 Base TX, EtherNet
Speed*: 10 Mb/s, 100 Mb/s
Access Mode:** Bus Master DMA
Buffer Size*: NA
Supported Connectors:** BNC, UTP

Known Problems

The latest Cogent EM110 adapters may require changing the Instance0.table to contain:
"Address Offset" = "20";
instead of
"Address Offset" = "0";

Driver Version Notes

3.32 - Added support for Cogent EM110-T4 adapters.
3.32 - Added remote kernel debug support.
3.35 - Added support for SMC EtherPower 10/100 B (9332BDT)

Macintosh: Structured Analysis & Design Programs (SSADM)

There is a VAX program called Structured System Analysis Design Methodology (SSADM), a generic term as well as the product name for the VAX program. It designs systems to run warehouses, handle orders and delivery notes, and so on. The program checks that the designer doesn't use variables with the same name in different areas and automates many other parts of the design process.

Is there a similar program available for the Macintosh?

This article has been archived and is no longer updated by Apple.
There are several programs for the Macintosh designed to help in Structured Analysis and Design. For more information, search in the Redgate Buyer's Guide Library using the search term "Case and Tools" or "Design and Tools".

EIDE/ATAPI Support in NeXTSTEP 3.3

This document discusses the various configuration options for the NeXTSTEP 3.3 EIDE driver, version 3.31.
This article has been archived and is no longer updated by Apple.

Overview

The EIDE driver version 3.31 for NeXTSTEP 3.3 supports ATA-1 and ATA-2 (X3T10 documents 791D and 984D respectively) conformant IDE hard disks and ATAPI compliant (SFF 8020 revision1.2) CD-ROMs.

The EIDE/ATAPI driver can be used in various modes (or personalities). These are the options available while installing NeXTSTEP or in Configure's Add Devices Panel.

1. EIDE and ATAPI Device
- full EIDE/ATAPI support
2. EIDE and ATAPI Device Controller for PC Tech RZ1000 PCI
- same as above but is optimized for RZ1000 PCI interface
3. Intel GX/Professional IDE Disk Controller
- only for Intel GX/Professional machines. Supports host-master DMA on these systems.
4. IDE Disk Controller
- provided for compatibility reasons

The EIDE/ATAPI drivers (1 and 2 in the list above) get the disk geometry from the drive itself. The IDE Disk drivers (3 and 4 in the list above) get the geometry from the BIOS instead. If you are installing NeXTSTEP you should always use the EIDE/ATAPI device drivers.

Features of the driver

+ Supports PIO mode 0 to mode 4 hard disks
+ Disks of size up to 8.4GB is supported by the driver
+ Primary and secondary controllers can be used
+ Supports up to two devices on each controller
+ Support for Logical Block Access (LBA) mode
+ Support for PCI IDE (32-bit data access, faster transfers)
+ Support for ATAPI CD-ROMs.

Configuring Hardware

The primary controller should be configured for port address 0x1f0-0x1f7 and irq 14. The secondary controller should use port address 0x170-0x177 and irq 15. You must enable primary and secondary (if applicable) controllers in your system BIOS.

IDE/EIDE Disks

ATA-1 and ATA-2 disks are supported by the driver. The driver uses the disk at maximum possible data rate. The IDE controller must support IOCHRDY (IO Channel Ready) line for a disk to be be used in Mode 3 or Mode 4. If your controller supports this line you should enable it in Configure. The driver uses the disks in multiple sector mode for better performance but you can disable this in Configure if desired. The EIDE/ATAPI drivers use LBA mode for disk access if the disk supports it.

ATAPI CD-ROM

ATAPI devices appear to the system as SCSI devices. Hence it is possible to install NeXTSTEP using an ATAPI CD-ROM and use it with other applications like CDPlayer.

If you are installing NeXTSTEP using an ATAPI CD-ROM you must connect the IDE hard disk and CD-ROM to the primary controller. The hard disk should be configured as master or as master with slave present (if this option is available). The ATAPI CD-ROM should be configured as slave. This is usually accomplished by changing a jumper on the device. After this you can proceed with NeXTSTEP installation in the usual way.

When prompted to select the SCSI adapter connected to your CD-ROM drive, select the Adaptec 154x SCSI driver to continue. When prompted for the type of disk controller the hard drive is connected to, select the EIDE and ATAPI driver. Once NeXTSTEP is installed you should remove the Adaptec154x driver with Configure.app. Requiring a SCSI driver to be loaded is a bug and will be fixed in a later version of NeXTSTEP.

Upgrading from an older IDE driver

The version of the IDE driver that shipped with NeXTSTEP 3.3 is version 3.30. The new EIDE driver is version 3.31.

1. If you are currently using the "IDE Disk Driver " you should upgrade to "IDE Disk Driver ".
2. If you are using the "IDE Disk Controller for large disks (> 504MB)" you should upgrade to EIDE/ATAPI driver.
3. If you are running with the special driver designed for Intel GX/Professional, you should use the new driver of the same name.

Bugs and Warnings

1. Disk drives and ATAPI CD-ROMs attached to the secondary controller are not available while installing NeXTSTEP due to system software limitations. However once NeXTSTEP is installed the secondary controller can be configured. You can do this by running Configure and adding the same driver again (set port address to 0x170-0x177 and irq to 15).

2. Due to a bug in Configure, primary and secondary ports must have the same personality of the driver. For example, you can not use IDE driver for the primary controller and EIDE driver for the secondary controller.

3. It is very important that the system BIOS recognize and be able to use all of the disk. Some BIOS's automatically do this when you power up the machine but for some you will have to do it yourself. Make sure that BIOS reports the actual disk size correctly (though the number of cylinders and heads may be different).

4. Some old BIOS's do not work with disks larger than 504 MB (1MB = 1 048 576 bytes). You can still use such disks with NeXTSTEP but not as a boot disk. A workaround is to connect this as a slave to a boot disk or on the secondary controller (if available). Or you can update your system BIOS.

5. You should attach ATAPI CD-ROMs to the secondary controller in your system (if available) for better performance.

6. ATAPI is an emerging standard and there are many incompatibilities in implementations. We recommend that you use ATAPI CD-ROMs as single master on a controller or as slave to an IDE disk. Many on-board PCI/VL-bus interfaces do not work very well with ATAPI CD-ROMs.

7. You should not switch between IDE drivers (3 and 4 in the list under heading Overview) and EIDE drivers. Since they get their drive geometries differently you may corrupt the data on your disk.

8. Different BIOS's implement LBA decoding differently. If you have DOS partition on an IDE disk and move it to a different system which also

supports LBA your disk might become unreadable or corrupt.

9. NeXTSTEP does not use BIOS for disk access except for booting. Therefore the BIOS must see the disk of the same size as the driver. In other words, if you are using a disk larger than 504 MB you must ensure that the BIOS recognizes all of the disk. You may need to enable "geometry translation" or its equivalent in the BIOS to do this.

10. Caching IDE controllers and add-on IDE controllers with BIOS on them are not supported.

11. Mode sense/select commands do not work for ATAPI devices.

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/DiamondStealth.pkg.compressed

Driver Name / Installer .pkg: DiamondStealthDisplayDriver
Driver Type: Display
Driver Scope: Product Family
Supported Components: S3 732 (Trio32), S3 764 (Trio64), S3 764 (Trio64V+), S3 801, S3 805, S3 864 (Vision), S3 868 (Vision), S3 911
PC Bus / Interface Supported by Driver:** PCI, VL-Bus

General Overview notes: This graphics driver is designed to support the VL-Bus & PCI versions of the Stealth 64 and Stealth 3D Graphics adapters from Diamond Computer Corp. These cards are based on the or S3-968, S3-868, S3-Trio, or ViRGE graphics controller chipsets and support 2MB or 4 MB of RAM.

This driver replaces the older Diamond Stealth64 driver.

Supported Products / Add-on Adapters:
Diamond Stealth 64 DRAM PCI-Bus Display Adapter
Diamond Stealth 64 DRAM VL-Bus Display Adapter
Diamond Stealth 64 Video PCI-Bus Display Adapter
Diamond Stealth 64 Video VL-Bus Display Adapter
Diamond Stealth 64 VRAM PCI-Bus Display Adapter
Diamond Stealth SE PCI-Bus Display Adapter
Diamond Stealth SE VL-Bus Display Adapter
Diamond Stealth 64 DRAM T PCI-Bus Display Adapter
Diamond Stealth 64 DRAM T VL-Bus Display Adapter
Diamond Stealth 64 Video VRAM VL-Bus Display Adapter
Diamond Stealth 64 Video 3200 VL-Bus Display Adapter
Diamond Stealth 64 Video 2121XL DRAM PCI-Bus Display Adapter
Diamond Stealth 64 Video 3000 VRAM PCI-Bus Display Adapter
Diamond Stealth 3D 2000 PCI-Bus Display Adapter
Diamond Stealth 3D 3000 PCI-Bus Display Adapter

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This driver does not support gamma correction in 16 and 24 bit modes. This results in a somewhat dim screen when using 16 bits per pixel. Also, in these modes the brightness slider in preferences is inoperative.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 1MB VRAM, 2MB DRAM, 2MB VRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
1024x768 (4MB+), 1152x864 (4MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 1152x864 (2MB+), 1280x1024 (4MB+), 1600x1200 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

· When used with the Diamond Stealth SE boards (both PCI and VL) configured for 800x600 8-bit Greyscale, some video artifacts and noise may be seen when viewing NeXTTIme movies or performing other graphics-intensive operations. One of the color modes is recommended if this occurs.

· Diamond has changed the PCI deviceID on their newer Stealth adapters. This will cause autodetection to fail, thus the NEXTSTEP driver will defualt

to VGA display mode. Under NEXTSTEP 3.3, the workaround is to click Expert... while inspecting the driver in Configure.app, then modify the value of the Auto Detect setting to read 0x88d05333 0x88d15333 0x88f05333.

· Diamond Stealth 64 Series 2001 does not use an S3 controller, it uses the ARK Logic which is not supported.

NeXTSTEP 3.3 Driver: ISA Serial Port

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.33, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/ISA_Serial_Port.pkg.compressed

Driver Name / Installer .pkg: ISASerialPort
Driver Type: System
Driver Scope: Generic-System
Supported Components: Intel i8250, Intel i82510, National Semi NS16450, National Semi NS16550, Startech ST16650
PC Bus / Interface Supported by Driver:** Integrated, ISA
Supported Connectors:
Access Mode: PIO
Adapter Memory: N/A

General Overview notes: This is a generic AT Compatible Serial Port Driver. It supports a variety of industry standard serial chips (UARTs), and can be configured for standard and non-standard configurations. This driver must be configured in order to use the Serial Pointing Device Driver and the Port Server Driver.

This driver replaces the SerialPorts driver shipped with NEXTSTEP 3.3

A/UX: Missing /dev/cXd0s3 File (9/94)

After loading A/UX, I needed to mount the slice 3 partition onto "/users." For some reason, when A/UX loaded, the /dev/dsk/cXd0s3 and /dev/rdsk/cXd0s3 drivers did not load (where "X" is the SCSI ID of the disk being loaded). I had to shutdown and change the SCSI ID before creating and mounting a file system on slice 3 for "/users." Why is this?

This leads to another problem: when installing, the Installer automatically modifies "/etc/fstab" to include an entry for "/usr" on slice 2 of the drive. Since I had to change the SCSI ID of the drive, the fstab entry was now incorrect. When I started up the system after changing the SCSI address, I got the message, "The file system on /dev/dsk/cXd0s2 is damaged. Do I want to repair?" When you say yes, it says it can't make the repairs, since of course it can't find the SCSI ID in "/etc/fstab". I went into "/etc/fstab" and changed the entry to match the new drive ID, which of course solved the problem.

Why doesn't the installer automatically create a "fs" on slice 3 and permanently mount it? Why weren't the "/dev/dsk/cXd0s3" and "/dev/rdsk/cXd0s3" files loaded?

This article has been archived and is no longer updated by Apple.
Did you follow a nonstandard or standard procedure when installing A/UX? For instance, if you follow a nonstandard procedure and create a separate "Usr" partition, the slice 2 is automatically assigned to that partition. From the error message above, it seems that the "Usr" on slice 2 was created by the installation process, but we're not positive what originally partitioned.

An output of "dp /dev/rdsk/cXd0s31" would help identify what partitions have been partitioned and what associated slices have been assigned.

In general, if a particular device driver entry was missing from the /dev/[r]dsk directory, you don't have to shutdown the system and change the SCSI ID. The entry is easily re-created by either entering the "mknod" or "pname" command. For example,

```
mknod /dev/dsk/c6d0s3 b 24 3
chmod 600 /dev/dsk/c6d0s3
chown bin /dev/dsk/c6d0s3
chgrp bin /dev/dsk/c6d0s3
```

Note that 24 is the major device number and 3 is the minor device number for /dev/dsk/c6d0s3. b is indicated as a block device type.

```
pname -c6 -s3 "/users"
```

The /dev/[r]dsk/c6d0s3 files will be automatically created in the /dev/[r]dsk directory. Note that "/users" is the partition name in dpme (disk partition map entries). Use "dp /dev/rds/c6d0s31" to see its exact spelling.

When using HD Setup for A/UX, the predefined A/UX partitioning schemes include three partition assignments. The partition named "A/UX Root" is assigned with slice 0, partition named "Swap" is assigned with slice 1 and a 4 MB Macintosh partition is defined. Remaining space is used for free UNIX slice 3. If the "custom" button is selected, other partitions and associated slice numbers can also be selected. For example, A/UX Usr partition will have slice 2, Free UNIX partition will have slice 3 through 6, and so on.

The reason that the installation process doesn't make a file system and permanently mount on these partitions is because the pre-assigned partition/slice may not be big enough to make a real file system (either SVFS or UFS).

NeXTSTEP for Sparc Hardware Q&A

Disclaimer

This document pertains to the NeXTSTEP operating system, which is no longer a supported product of Apple Computer. This information is provided only as a convenience to our customers who have not yet upgraded their systems, and may not apply to OPENSTEP, WebObjects, or any other product of Apple Enterprise Software. Some questions in this Q&A document may not apply to version 3.3 or to any given specific version of NeXTSTEP.
This article has been archived and is no longer updated by Apple.

SPARCstation4 Known Problems

Q: After installation, why does my SPARCstation4 hang with ""localhost loginwindow Could not find WindowServer port!" messages?

A: NEXTSTEP does not support the optional video SIMM on SPARCstation4's. You must remove this SIMM for NEXTSTEP to work.

Solaris and NEXTSTEP

Q: Can NEXTSTEP be installed on a Sun which has other disks for Solaris attached to it?

A: Yes, it is possible to have NeXTSTEP installed on an external disk while maintaining Solaris on the internal disk.

Q: Does the NEXTSTEP disk have to be the one with the lowest SCSI ID?

A: No, NEXTSTEP can be installed on any disk with a valid SCSI ID. Generally, a SPARCstation internal disk is always at SCSI ID 3. External disks under SPARC may use SCSI ID 1, 2, or 5. SCSI ID 4 is generally used for tapes, and CD-ROM drives are generally at SCSI ID 6, but this is changeable.

Q: Is there a good way to toggle which disk/OS to boot?

A: You can specify which disk to boot in the Sun ROM monitor with **boot diskX** where X is the disk from which to boot. To see a list of SCSI devices on the system and their corresponding disk numbers, use the **probe-scsi** command at the Sun ROM monitor.

Also, if you wanted to set up the system to always default to booting from NEXTSTEP, you could set the NVRAM parameter as follows:
setenv boot-device diskX

Q: Is it possible to access Solaris files from NEXTSTEP, and vice versa?

A: No, you cannot mount a Solais UNIX filesystem from NEXTSTEP or vice versa. You can mount CDs intended for Solaris since they are ISO-9660 format.

Q: Okay, I've set up a dual-boot machine using one disk for NEXTSTEP and another for Solaris. Whenever I log in under NEXTSTEP, I get a panel which says "This disk is damaged: initialize?" with options to initialize, repair, or ignore. The default option is "Initialize." What should I do?

A: This happens because NEXTSTEP attempts to mount the Solaris disk but does not know how to read its filesystem. You should click "Ignore." *Choosing either of the other options may result in irreparable data loss on the Solaris disk.*

This can be avoided by adding an entry in **/etc/fstab** that will force NEXTSTEP to ignore the Solaris disk automatically. The disk type for the Solaris disk should be 'ignore'. See the mntent(5) UNIX manual page for more information.

Installing Solaris over NEXTSTEP

Q: Solaris 2.x can't format a disk on which NEXTSTEP was installed. Solaris complains about a trashed label.

A: Solaris expects the hard disk to be labeled a certain way. If you drop back a few versions of Solaris, it will work using

an old version of Sun's formatter/installer. A work around is to use SunOS 4.1.x to reformat and then install Solaris 2.x. Another solution is to boot single user with NEXTSTEP from a CD, run **sdform /dev/rsd0a**, boot off the Solaris CD with **boot cdrom /kernel/unix**, abort the install and run format. Then run **suninstall**.

CD-ROM Compatibility

Q: What CD-ROM drives can be used to install NEXTSTEP?

A: Due to restrictions with Sun hardware, only Sun CD-ROM drives can be used to install NEXTSTEP.

Q: Can a wider range of CD-ROM drives be used to read CD-ROMs once NEXTSTEP has been installed?

A: Yes.

OBP ROM Compatibility

Q: What version of OBP ROMs must my SPARCstation have to run NEXTSTEP 3.3?

A: Machines with OBPs before version 2.12 will hang during boot. To run NEXTSTEP on a systems with an OPB version before 2.12, the OBP ROMs must be upgraded. Customers should contact SUN for additional details.

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/MatroxMGA2064W.pkg.compressed

Driver Name / Installer .pkg: MatroxMGA2064WDisplayDriver
Driver Type: Display
Driver Scope: Specific Product
Supported Components: Matrox MGA1064SG (Cyclone), Matrox MGA1164SG (Hurricane), Matrox MGA2064W (Storm), Matrox MGA2164W (Mistral), TI TVP3026 RAMDAC
PC Bus / Interface Supported by Driver:** AGP, PCI

General Overview notes: This graphics driver is designed to support the MGA Millennium and Mystique Graphics adapters from Matrox Graphics Inc. It may also support other adapters based on the MGA1064SG, MGA1164SG, MGA 2064W and MGA 2164W Graphics controller chipset from Matrox.

This driver supports the use of 2MB or 4MB of SGRAM for the MGA1064SG based adapters; 2MB, 4MB or 8MB of SGRAM for the MGA1164SG based adapters; 2MB, 4MB, or 8MB of WRAM for the MGA2064W based adapters; and 4MB, 8MB, 12MB, or 16MB of WRAM for the MGA2164W based adapters.

Supported Products / Add-on Adapters:
Matrox MGA Millennium
Matrox MGA Millennium II
Matrox MGA Millennium II AGP
Matrox Mystique
Matrox Mystique 220
Matrox Mystique 220 AGP

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 1800x1440 (4MB+), 1920x1080 (2MB+), 1920x1200 (4MB+), 640X480 (1MB+)

Known Problems

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.31) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.30 - Initial Release of this Driver
3.31 - Added support for multi-headed displays and 8MB WRAM
3.34 - Fixed bugs in PLL locking code. Added 85Hz modes. Added HDTV resolutions.
3.36 - Added support for the MGA2164W (Millennium II) chipset.
3.37 - Updated pixel/system clock routines, and EPROM parsing.

A/UX: How To Figure Swap Partition Sizes

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

Can you recommend a good size swap partition for best performance under A/UX? I'm using a 200MB drive and have a Macintosh IIfx with 20MB, though I'm also interested in recommendations for a 32MB Macintosh IIfx system.

Also, is there any formula (physical RAM +10MB, for instance) for determining a good swap size? I assume the swap size should be larger than the physical RAM in the system.

This article has been archived and is no longer updated by Apple.
The size of swap space should be larger than the physical memory size. Actually, there is no magic "formula".

A standard version of A/UX 2.0, based on an A/UX with 8MB of physical memory, has about 18MB of disk space allocated for swap purposes. 18MB is twice as much as the physical memory. Therefore, if disk space is not a restraint, we recommend two to two and a half times the physical memory size be assigned for swap space. If disk space is a concern, less than twice of physical memory size may be allocated for swap space.

Note that the swapping in and out activity occurs only when the available physical memory is used up. If your applications require large amounts of memory allocation, you should increase the swap size. Use the "swap -l" to view the current free swap size. If you have a reserved A/UX partition, you may use the "swap -a ..." to add additional swap area.

LaserWriter IINTX: System Printer with VAX Host

How do I use a LaserWriter IINTX printer as system printer for a VAX host?

I'm looking for general pointers, including PATHWORKS, and some comparison shopping tips, such as equipment, labor and training requirements to install and support this kind of printer.

This article has been archived and is no longer updated by Apple.
PATHWORKS for Macintosh has a VAXshare Print service that does what you want.

VAXshare print servers work very much like AppleShare print servers. When you send a document to a VAXshare print server, VAXshare receives the file's contents. The server then prints instructions from your Macintosh application and saves a print file on the disk. VAXshare returns the printer codes to your application to signal that printing is done.

VAXshare print servers access both Apple and Digital PostScript network printers. Since the LaserWriter IINTX has to be on a LocalTalk network, you'll need a router between EtherTalk and LocalTalk. Examples of routers include the Apple Internet Router, Shiva FastPath, Farallon Liaison, Cayman GatorBox, or devices that connect the LaserWriter II printer to Ethernet, such as EtherPrint.

After installing PATHWORKS on a VAX, the system manager goes into the MSA$MANAGER program, adds a printer queue, and starts it. These printer queues are standard VMS queues, so they work the same way as other existing VMS queues (using SET QUEUES, START, and STOP QUEUES commands). VMS users also can print to these queues with the PRINT/QUEUE= command.

On the Macintosh side, selecting a VAXshare print spooler is similar to selecting an AppleShare Print Spooler. From the Chooser, select the zone (if necessary) then select the LaserWriter icon from the group of icons on the left side of the Chooser window.

There shouldn't be much training needed for doing this. On the VAX side, VMS System Managers are familiar with VMS queues, and installation on the VAX is done with standard VMSINSTAL. Macintosh users need only choose the standard printer/spooler name.

The only issue is the amount of printing you'll be doing. If there will be much printing that doesn't require laser quality, then a standard line printer might be all you need.

Applesoft Internals: Using Applesoft ROM Subroutines (1 of 2)

The following notes, first published in The Apple Orchard (March 1980) are written for experienced 6502 machine language programmers who wish to use the Applesoft ROM subroutines. The addresses given are for an Apple II+ with an Applesoft firmware card, or Applesoft loaded into a Language Card.

Consult your Applesoft Reference manual for more information.
This article has been archived and is no longer updated by Apple.
Take special note of CHRGET, the heart of Applesoft. When Applesoft wants the next character of an instruction, it points TXTPTR at the program or input buffer, and JSRs to CHRGET. TXTPTR is temporarily set to the last used DATA statement when Applesoft READS DATA.

ABBREVIATIONS

msb: most significant bit or byte
lsb: least significant bit or byte
eol: end of line token ($00)

A: the 6502 accumulator
X: the 6502 X register
Y: the 6502 Y register
Z: the zero flag of the 6502 status register
C: the carry flag of the 6502 status register

A,X is a 16 bit number where A has the msb and X the lsb.

(Y,A) is the number or string whose address is in Y and A, with the msb in Y and lsb in A.

FAC: the floating point accumulator
ARG: the ARGument register

TXTPTR Routines

CHRGET 00B1
CHRGET increments TXTPTR. Use CHRGOT to get the character. TXTPTR now points at:

CHRGOT 00B7
CHRGOT loads A from TXTPTR and sets certain 6502 status flags. X and Y are not changed. On exit:

A = the character currently pointed at by TXTPTR
Z is set if A is ":" or eol ($3A or $00)
C is clear if A is an ASCII number("0" to "9").

LINGET DA0C
LINGET read a line number (integer 0 to 63999) from TXTPTR into LINNUM. LINGET assumes the 6502 registers and A have been set up by the JSR to CHRGET that fetched the first digit. LINGET normally exits through CHARGET, which fetches the character after the last digit. When the number is greater than 63999, LINGET exits via SYNTAX ERROR. LINNUM is zero when there is no number at TXTPTR.

GTBYTC E6F5
GTBYTC causes JSR to CHRGET to gobble a character, then evaluates the formula at TXTPTR, and then it returns a single byte integer in X and FACLO. On entry TXTPTR points to the first character of the formula. GTBYTC normally exits through CHRGET. If FAC is greater than 255 or less than 0, it exits through ILLEGAL QUANTITY ERROR.

GETBYT E6F8
GETBYT evaluates the formula at TXTPTR besides returning a single byte integer in X and FACLO. On entry, TXTPTR points to the first character of the formula. GETBYT normally exits through CHRGET. When FAC is greater than 255 or less than 0, it exits through ILLEGAL QUANTITY ERROR.

PLOTFNS F1EC
PLOTFNS gets two LORES plotting coordinates separated by a comma from TXTPTR (0-47,0-47). TXTPTR when entered, points to the first number of the formula. PLOTFNS puts the first number in FIRST and the second number in H2 and V2.

HFNS F6B9
HGNS gets HIRES plotting coordinates (0-279,0-191) from TXTPTR. TXTPTR points to the first character of the formula for the first number

upon entry. HFNS leaves the 6502 registers set up for HPOSN. When exiting:

A = vertical coordinate
X = lsb of horizontal coordinate
Y = msb of vertical coordinate

Device I/O Routines

INLIN D52C
Input a line of text without sending out a prompt from the current input device into the input buffer, BUF. INLIN uses GDBUF to strip off the most significant bit on all input characters.

INLIN+2 D52E
Input a line of text prompting with the character in X from the current input device into the input buffer, BUF. INLIN uses GDBUF to strip off the most significant bit on all input characters.

GDBUFS D539
Puts a zero at the end of the input buffer, BUF, and masks off the msb on all bytes. On entry: X = the end of the input line.
On exit:

A = 0
X = FF
Y = 1

INCHR D553
Get one character from the current input device in A and mask off the MSB. INCHR uses the main Apple input routines and supports normal handshaking.

STROUT DB3A
Print string pointed to by Y,A. The string must end with a null or a quote.

STRPRT DB3D
Print a string whose descriptor is pointed to by FACMO,FACLO.

OUTDO DB5C
Print the character in A. INVERSE, FLASH, and NORMAL in effect.

CRDO DAFB
Print a carriage return.

OUTSPC DB57
Print a space.

OUTQST DB5A
Print a question mark.

INPRT ED19
Print " IN " and the current line number from CURLIN. Uses LINPRT.

LINPRT ED24
Prints the 2 byte unsigned number in X,A.

PRNTFAC ED2E
Prints the current value of FAC. FAC is destroyed. Uses FOUT and STROUT.

Lisa Basic+ 2.0

This article has been archived and is no longer updated by Apple.

You might expect the German umlaut, not a standard ASCII character, to get the interperter to generate a syntax error. Instead, the system hangs as if it were in an infinite loop; use the "pc 0" in the debugger to return to the command line. Avoid using option characters within the program text.

If a missing "&" in a multiline statement generates a syntax error instead of a system hang, something else may be wrong with the statement or with the system itself.

The renumbering of embedded numbers in 'REM' statements is often unsuccessful. Usually, the problem is that the number embedded in the 'REM' statement is both (a) the same as a line number in the program before or after the 'REM' statement itself, and (b) also a number that would be used in the renumbered sequence.

Lisa Basic+ supports two types of arrays, virtual and non-virtual (i.e. resident in memory). Both virtual and non-virtual arrays contain a limited number of elements: 2730 for real arrays and 16383 for integer arrays. (See the Basic+ User's Guide, page 9-2.) The system allocates a maximum of 32K of system memory to each non-virtual array dimensioned. Use the "LENGTH" command to tell you how much memory is available. With that amount, calculate the number of arrays you can dimension within the specific program.

Virtual array files (disk based) as well as arrays within the file can occupy more space than the available system memory. An example:

The maximum number of non-virtual arrays of maximum size with 504K of available memory is 16. Yet, if the program utilizes virtual arrays, the number of arrays that can be dimensioned is limited only by the amount of free disk space.

You can delete a file from within a basic program using the system statement 'Kill'. Refer to page 14-3 in the Basic Language manual for more details.

To transfer files with the file-manger to Slot 2 Channel 2:
1) press f for file-manager.
2) press t for Transfer.
3) in response to:
WHERE?
type -slot2chan2-

APPLE-. does terminate a LisaBasic program at the next logical stopping point; you can cause the program to resume by typing CONT. (Refer to page 3-11 in the Basic Language manual for details.) This method will NOT work, however, with a system hang due to, for instance, as an infinite loop; in such a case, you must implement the debugger in order to escape.

A/UX: How To Get Classic Terminal Logon Screen at Launch (8/94)

Is it possible to launch A/UX so that a classic terminal logon screen comes up without having to use the Macintosh logon screen?

This article has been archived and is no longer updated by Apple.
Yes, and here's how:

* Modify the /etc/inittab file to have the "co" entry execute a different shell script (for instance /etc/unixlogin below) instead of /etc/loginrc (executes the Macintosh Login)

or

* Make the /mac/bin/Login program nonexecutable or nonexistent by renaming it. The /etc/loginrc shell script checks to see if /mac/bin/Login is executable. If not, it will execute "/etc/getty" instead of /mac/bin/Login.

```
#!/bin/sh
# /etc/unixlogin
/bin/screenrestore
exec /etc/getty console co_9600
```

Norton Utilities: Can‘t Override Empower Encryption

Can Norton Utilities bypass Empower and Fileguard security? Can Norton read folders and files protected by security software packages?

This article has been archived and is no longer updated by Apple.
Using the Norton Emergency disk, we could recover deleted files protected by Empower. All of these files were still encrypted, unreadable, and useless. Sometimes the file types no longer matched the original.

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/ES1x88Audio.pkg.compressed

Driver Name / Installer .pkg: ES1x88AudioDriver
Driver Type: Sound
Driver Scope: Generic-Chipset
Supported Components: ESS Tech ES1688, ESS Tech ES1788, ESS Tech ES1868, ESS Tech ES1888
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This driver is designed to support on-board and add-on audio implementations based on ESS688, ESS1788 ESS1868, and ESS1888 chipset.

Supported Products / Add-on Adapters:
NewCom High Fidelity 16i E5X1853

Supported Products / Systems (ie integrated into PC System):
Compaq Prolinea
NEC Versa 4000
DEC Celebris GL & GL/ST

Special Features of Driver / Driver Notes:

AppleShare: Modification Date Depends On Client‘s Clock

We have an AppleShare File Server. One morning, a user put a file at the root level. On his machine, the file correctly showed a modification date of 21 February.

When the server volume was mounted on another Macintosh, the modification date showed up as 18 February. We noticed that this Macintosh's clock was set to 18 February. When we reset the clock to the correct date, the modification date changed back to 21 February.

What's going on here? The date on any single machine should not affect the date that shows up for the file. Shouldn't the server be giving the creation date? Why would the Finder show the wrong date?
This article has been archived and is no longer updated by Apple.
This is not a bug and is intentional. Here is some text from "Inside AppleTalk, Second Edition," pages 13-21 and 13-22, that discusses this subject:

Date-time Values

"All date-time quantities used by AFP specify values of the server's clock. These values correspond to the number of seconds measured from 12:00 AM on January 1, 2000. In other words, the start of the next century corresponds to the date-time of 0. AFP represents date-time values with 4-byte signed integers."

"One of the AFP calls, allows the workstation to obtain the current value of the server's clock. At log on time, the workstation should read this value (s) and the value of the workstation's clock (w) and compute the offset between these values: s-w. All subsequent date-time values read from the server should be adjusted by subtracting this offset from the date-time. All subsequent date- time values sent to the server should be adjusted by adding this offset to the date-time. This adjustment will correct for differences between the two clocks and will ensure that all workstations see a consistent time base."

One thing to note here is with Apple's AFP servers, the time base is not adjusted if the workstation's clock and server's clock are within 15 minutes or so of each other. This is done so slight differences between the workstation's clock and the server's clock settings do not affect the file date-time values. If the time difference is more than 15 minutes, the time is adjusted to the nearest half hour. For example, if the server clock is 20 minutes ahead of the workstation clock, the date-time value for a file would be 30 minutes less on the workstation. Non-Apple AFP servers may do this differently.

Some Examples

Note: These examples assume the time zone values are set correctly on the server and the client unless otherwise specified.

* Example 1:
There is an AppleShare File Server in New York and its clock says it is 4:01 PM. There is an AppleShare client in Los Angles that is logged into the server in New York and its clock says it is 1:00 PM. A "Get Info" is done on file "X" by someone in New York on the New York server and the created and modified date-time says:

"Wed, Mar 4,1992, 7:07 PM"

At the workstation in Los Angeles, a "Get Info" is done on file "X" on the New York server, and the created and modified date-time says:

"Wed, Mar 4,1992, 4:07 PM".

As you can see, the client in Los Angeles shows the file created and modified date-time stamp as being 3 hours earlier.

* Example 2:
There is a AppleShare File Server in San Jose and its clock says it is 8:21 PM. There is a AppleShare client, also in San Jose, that is logged into this server and its clock says it is 8:00 PM. A "Get Info" is done on file "X" at the server and the created and modified date-time says:

"Wed, Mar 4,1992, 7:07 PM".

The client does a "Get Info" on file "X" and the created and modified date-time says:

"Wed, Mar 4,1992, 6:37 PM".

If the client's clock had been within 15 minutes of the server's clock, the file would have had the same date-time stamp.

All of our testing regarding this date-time stamping issue shows that the actual time shown in the "General Controls" or "Date & Time" Control Panel is what is used to compute the date-time offset between the client and the server.

LaserWriter Performance: Color/Gray Scale vs Black & White

Does changing a LaserWriter's default dialogue box from color/gray scale to black and white improve printing performance? Can I use ResEdit to do this, or is there another way to change the default?

This article has been archived and is no longer updated by Apple.
On AppleLink, in the Tech Info Library, you will find a patched version of the LaserWriter 6.0.1 driver that defaults to black and white. Use the search criterion of "LaserWriter 6.z.1".

The LaserWriter 6.0.x drivers, when in "Black & White" mode, print black and white documents as fast or slightly faster than the LaserWriter 5.2 drivers. This is true for both text or graphic documents.

The LaserWriter 6.0.x drivers, when in "Color/Grayscale" mode, are as much as 8 times slower than the LaserWriter 5.2 drivers. Black and white text-only documents will print as if the "Black & White" mode was selected. The "Color/Grayscale" mode should be used only in situations where you are printing documents that are multicolor or gray scale images.

The LaserWriter 6.0.x drivers default to "Color/Grayscale" mode, so you'll have to change the setting every time you print if they want to use "Black & White" mode.

Macintosh: When Application Colors Change Unexpectedly

I have a Macintosh IIsi with 5MB of memory, a 13-inch High Resolution color monitor with built-in video, 40MB hard disk, and NuBus adapter.

My problem appears randomly, always when running these applications: Telnet 2.3, Microsoft Word 4.0b, and Microsoft Excel 2.2a.

In Excel, when I call up a dialog box (to set borders, for example) the colors of the box will be messed up. If I keep reopening the dialog box the colors will eventually change. For example, the box may initially come up with a black background and black letters, then a blue background with black letters, than a red background, with black letters, and so on.

This article has been archived and is no longer updated by Apple.
It sounds like something is changing the System color table. We have experienced this when using the Kolor CDEV (the CDEV that allows you to change the color of the windows, buttons, scroll bars, and so on). If you're running MultiFinder, one of your applications may be setting the System color table to its own custom palette. 4th Dimension, for example, can change the System's color table.

Your workaround depends on whether it's an application or a CDEV that's changing the color. If it's something like Kolor, turning it off may be the only solution. Or perhaps there's been an update to the CDEV--check with the publisher for the latest version. With 4th Dimension, some people have used ResEdit to eliminate the offending resource. But this causes some applications to crash, so we don't recommend this solution.

Also, reinstalling the System may be a solution. It could be that your System color table has simply been corrupted.

NeXTSTEP 3.3 Patch 1 Overview

The NEXTSTEP Release 3.3 Patch 1 is a series of packages and scripts that provide fixes to several bugs introduced in NEXTSTEP Release 3.3. Please read the **Release Notes** and **Release Notes Addendum** thoroughly before applying the patches.

Caution: *These packages should only be installed on systems running NEXTSTEP Release 3.3.*

*****Do NOT install this patch on systems running NEXTSTEP 3.3J (Kanji Version). NEXTSTEP 3.3J incorporates the updates that this patch provides.**
This article has been archived and is no longer updated by Apple.

Packages:

The *NEXTSTEP Release 3.3 Patch Update* consists of two User Patch packages:

3.3Intel68kPatch.pkg, available from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/3.3_Patch_1/3.3_Int_68k_Patch1.tar

Contains updated system software for Intel PCs or NeXT computers running *NEXTSTEP Release 3.3*.

3.3HPPASPARCPatch.pkg, available from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/3.3_Patch_1/3.3_HP_SPARC_Patch1.pkg.tar

Contains updated system software for Sun or HP workstations running *NEXTSTEP Release 3.3*.

and one Developer Patch package:

3.3DeveloperPatch.pkg, available from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/3.3_Patch_1/3.3DeveloperPatch.pkg.tar

Contains updated developer tools for all types of computers running *NEXTSTEP Developer Release 3.3*.

In addition, the *NEXTSTEP Release 3.3 Patch Update was updated to include*:

3.3Patch.ImprovedDNS.post_install, available from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/3.3_Patch_1/3.3_Patch1_DNS_PostInstall

An installation script for improved DNS lookups.

3.3Patch.LibrariesOK.post_install, available from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/3.3_Patch_1/3.3_Patch1_Libs_PostInstall

Another installation script, for users with POSIX apps that can not be rebuild with the new libposix.a

libposix.a

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/3.3_Patch_1/libposix.a

The POSIX static library, for building posix applications for 3.3patch1 machines using **gethost*()** libc routines. Install as **/usr/lib/libposix.a.**

NeXTSTEP 3.3 Patch 1 Release Notes

This document describes how to install the *NEXTSTEP Release 3.3 Patch Update* and describes the fixes contained in the update. This update is to be installed *only* on computers running *NEXTSTEP Release 3.3*. Your existing NeXT Software License Agreement governs the use of this software update.

For download and distribution information, see the **NeXTSTEP 3.3 Patch 1 Overview**.
This article has been archived and is no longer updated by Apple.

INSTALLING THE NEXTSTEP RELEASE 3.3 PATCH UPDATE

The *NEXTSTEP Release 3.3 Patch Update* consists of two User Patch packages:

3.3Intel68kPatch.pkgPContains updated system software for Intel PCs or NeXT computers running *NEXTSTEP Release 3.3*.

3.3HPPASPARCPatch.pkgPContains updated system software for Sun or HP workstations running *NEXTSTEP Release 3.3*.

and one Developer Patch package:
3.3DeveloperPatch.pkgPContains updated developer tools for all types of computers running *NEXTSTEP Developer Release 3.3*.

Note the following points before you install the Patch Update packages:

Install just one package at a time. Install the User Patch package first; afterwards, install the Developer Patch package (if you're running *NEXTSTEP Developer Release 3.3*).

If you plan to use Emacs, be sure you've already installed the contents of the **Emacs.pkg** (contained on the *NEXTSTEP Release 3.3* CD-ROM) *before* installing the User Patch package.

When installing the Release 3.3 Patch Update packages, select the same architectures and languages as you did when originally installing the *NEXTSTEP Release 3.3* and *NEXTSTEP Developer Release 3.3* software.

Installing the NEXTSTEP Release 3.3 Patch Update Packages

Follow these instructions to install the *NEXTSTEP Release 3.3 Patch Update*.

1. Log in as **root**. (If you're not sure how to log in as **root**, see your system administrator.)

2. Make sure your computer is running *NEXTSTEP Release 3.3*. (You can find the NEXTSTEP version number with the Workspace Manager application's Info Panel command.)

Warning: Installing the *NEXTSTEP Release 3.3 Patch Update* on a computer that isn't running *NEXTSTEP Release 3.3* will result in unexpected issues.

3. Double-click the **3.3Intel68kPatch.pkg** file or the **3.3HPPASPARCPatch.pkg** file (be sure to choose the one that corresponds to the type of computer you're installing the package on).

4. Click the Install button in the Installer package window.
An Install Package panel opens. Use this panel to select the same architecture and languages as you did when originally installing the *NEXTSTEP Release 3.3* software.

5. Click Install in the Install Package panel, and if prompted for confirmation, click OK to proceed.
The Installer window displays information about the progress of the installation, which may take several minutes.

6. After Installer finishes installing the User Patch package:

192201_smBlksquare.tiff , If you *haven't* previously installed *NEXTSTEP Developer Release 3.3* on the computer, you're donePlog out and restart the computer.

340938_smBlksquare.tiff , If you *have* previously installed *NEXTSTEP Developer Release 3.3* on the computer, install the Developer Patch package by double-clicking the **3.3DeveloperPatch.pkg** file and repeating steps 4 and 5 (remember to select the same architectures as you did when originally installing the *NEXTSTEP Developer Release 3.3* software). Afterwards, log out and restart the computer.

NEXTSTEP Release 3.3 Patch Update Release Notes

The remainder of this file describes the new features and bug fixes that comprise the *NEXTSTEP Release 3.3 Patch Update*.

New Features

The following new features have been introduced in this update:

Faster HPPA compiler. A faster compiler for NEXTSTEP for PA-RISC workstations has been included in this release.

Issues Fixed in This Release

The following issues have been fixed in this update:

Drivers

Reference: 45838, 54418, 54461, 54462
Issue: HCRX & HCRX24 cards are not supported.
Fix: The new Hyperdrive graphics cards (HCRX and HCRX24) are now supported. Note that although the HCRX card is only 8 bits deep, it can be run in "color-recovery" mode as a 24-bit device. If you are running the HCRX card as the console boot device in 8-bit color mode, turn off boot graphics in your configuration to obtain the proper color map.

Reference: 50481
Issue: MIDI driver doesn't load.
Fix: This has been fixed.

Reference: 52993
Issue: When an HP computer running NEXTSTEP Release 3.3 boots with the serial driver configured, a getty turned on for a serial port, and the modem connected and turned on, the system panics.
Fix: This has been fixed.

Reference: 54419
Issue: On HPPA machines, choosing 8-bit color leads to color glitches.
Fix: 8-bit color modes had issues with bad color map entries. This has been fixed. Note, however, that a related bug (#54420) has not been fixed. This bug arises when you change the brightness on multi-headed HP 715'sPit causes color map glitches on 8-bit displays. The issue seems to occur only after power cycling and booting with boot graphics. Booting verbosely should avoid the issue.

gdb

Reference: 24436
Issue: gdb does not interpret floating point numbers correctly when specified as message arguments.
Fix: This has been fixed.

Reference: 50727, 54401
Issue: gdb occasionally hangs or panics when used with certain applications.
Fix: This has been fixed.

Reference: 52634
Issue: gdb's *step: command behaves like *next.:
Fix: *step: now steps *into* methods, instead of stepping over them.

Reference: 54968
Issue: Stack frames in gdb's browser are reversed.
Fix: Between NEXTSTEP Release 3.2 and Release 3.3 the top-to-bottom order in which stack frames are listed in the Edit/Browser tool were inadvertently reversed, so that the outermost function appeared at the bottom instead of the top. This was not done in an internally consistent way, so that if you clicked on the third stack frame from the bottom, for instance, Edit took you to the third one from the top. This has been fixed so that it works the way it did in NEXTSTEP 3.2.

Kernel

Reference: 51192
Issue: Cached kmsgs are not properly initialized
Fix: When using a cached kmsg, the ikm_delta field was not being initialized. This is especially important in the exception handing code when sending the exception message. Cached kmsgs are now properly initialized.

Reference: 54071
Issue: Certain procedures can cause the kernel to hang due to an ipc hash leak.
Fix: This has been fixed.

Libraries

Reference: 54173, 54399
Issue: libc's exp() gives incorrect results on Intel-based computers.
Fix: This has been fixed.

Reference: 54226
Issue: _openDefaults can leak 1024 bytes per invocation.
Fix: This has been fixed.

Reference: 54674
Issue: longjmp should preserve the FPU control word across fninit
Fix: This has been fixed.

Networking and Networking Tools

Reference: 54180
Issue: Packet size negotiation logic is flawed.
Fix: NetWare performs packet size negotiation during the server discovery process. This negotiation process is flawed. For example, suppose that the client station first sent its favorite packet size (1024 bytes for Ethernet, for example) to the server on the other side of a LAN switch. The server would then send back its favorite packet size (say, 4096 for FDDI) which the client simply accepted as the negotiated block sizePdespite the fact that this size is illegal for Ethernet. This issue arose because neither the server nor the client are aware of the existence of the LAN switch that is bridging the FDDI and Ethernet LANs.

The patch causes the workstation to ignore negotiated packet sizes larger than what its immediate medium can support.

This should be sufficient until such time as NeXT implements "burst mode" transfers.

Reference: 54216
Issue: Network socket `bind' fails to detect *address in use.:
Fix: A bug was introduced during the porting of Stanford's IP Multicast code that allowed multiple local clients to bind to the same IP address (that is, the code failed to detect that the address was in use). This patch corrects that error.

Reference: 36740, 39778, 49580, 49585, 49607, 49899, 50175, 51088, 51809, 51944, 53423
Issue: Various netinfo bugs.
Fix: A number of bugs were fixed in netinfo. The following are some of the more notable bugs that were fixed:

39778: *If you have a second account with a uid of 0, netinfo authentication can fail.* If a netinfo domain had multiple users with the same UID, authentication for that UID would be unreliable.

49607: *lookupd should number domains starting at 1.* Minor change. When lookupd received a SIGUSR2 to log it's current connections, it numbered domains started at 0 rather than 1.

49899: *Permission denied even when _writers is* *. Directories with **_writers *** were only writable by root.

50175: *nidomain must byte-swap master's address.* This bug caused **nidomain -c** to fail to create clones on Intel-based computers. The master's IP address was byte-swapped, resulting in an incorrect and unusable database.

51088: *Memory smasher in netinfod.* This bug would cause random netinfo crashes. It was the result of **ni_writeprop()** freeing some memory twice.

51809: *netinfod[PID]: tag test: can't get masters /machines/ip_address/I^AT*s^ directory.* The netinfo clone start-up configuration checking routine had a couple of syslog messages that were missing an argument. If a clone was mis-configured, it would print a garbled error message.

51944: *file name is freed, then used.* A very rare bug that only occurred if a file system error occurred while the server was shutting down, and it got an error while writing the checksum file.

53423 *netinfod shouldn't call ni_error() - localization calls getpwuid()*. A rare bug that could cause netinfo to hang before printing an error message if it detected an internal error.

Reference: 54242
Issue: NetInfoManager won't create clones on Intel-based computers.
Fix: This bug prevented NetInfoManager from creating clone netinfo servers on Intel-based computers. The bug affected clone creation using both the *Servers: panel and the *Manage Hierarchy: panel. Clones created using NetInfoManager would have the master's Internet address reversed, and as a result database initialization and updates would fail. This has been fixed.

Issue: SimpleNetworkStarter messes up mail server configurations.
Fix: This bug caused SimpleNetworkStarter to install its mail-server package every time it ran. The result was that the last computer that was configured using SimpleNetworkStarter would really be the mail server. Confusing information would be left behind on other computers, and mail would not be correctly configured. This has been fixed.

Issue: netinfo's clone self-check has RPC issues.
Fix: This bug caused sporadic start-up issues on clone netinfo servers. The bug was caused by errors in the clone configuration self-check routines that ran at start-up time. These self checks have been disabled in this update.

Software Localization

Reference: 49523
Issue: There is no Colors.. menu item in localized versions of Terminal.
Fix: This has been fixed: the Colors command is now present in the localized versions of Terminal.

Reference: 49525, 49559, 50876, 51668, 52463
Issue: Various cosmetic fixes are needed for localized text:

Raising the color panel from any application while you are working in a language other than English produces a *parse error: message in the console window (and the panel contains English text).

The window title that is displayed while loading Preferences is in English, even when you are working in a language other than English.

When working in French, Configure's Inspector.nib shows some English text.

When working in French, some configuration text fields aren't wide enough to contain entire sentences.

The Spanish version of Loginwindow's preferences panel is poorly formatted.
Fix: Several of the localized Preferences, Configure, and SimpleNetworkStarter files were fixed to provide cleaner UI.

Reference: 50792, 50794, 51190, 54229, 54279
Issue: UserManager has a number of bugs in the various localized versions:

The User Info confirmation panel does not display the path of the login shell when you are working in French.

The Program Hooks pop-up menu has no valid labels in the Group Default Configuration panel when you are working in French.

Some fields in the Create Bulk panel aren't properly localized.

Clicking on the User Account login name format pop-up list after creating multiple users in a domain and then reading an input file containing user names causes UserManager to crash.

This issue still exists when running UserManager in Swedish on Intel or NeXT architectures. As a workaround, run UserManager in another language.

The Group menu doesn't work when working in German.
Fix: This patch release fixes some connections in the nib files for the localized versions of UserManager so that now creating bulk accounts, creating groups, and inspecting group defaults all work properly in the localized versions.

Reference: 51223
Issue: You cannot choose a language other than English when you create a new user account.
Fix: New template files were added so that system administrators will be able to create new user accounts with certain localization defaults already set. If you are a system administrator and would like to use User Manager to create new user accounts with defaults localized for French, German, Italian, Spanish, or Swedish, you need to select all of the languages when you install the patch. This will ensure that all of the default files are available for your use in **usr/template/languages**.

Note that this will also install other updated language files that are included on the patch. If you use Preferences to select another language that has not been previously installed from the original release software, these updated files would appear in that language while the rest of the UI files in a particular application would appear in the next language you have selected in Preferences which has been installed.

A related bug still exists, however: if you install NEXTSTEP Release 3.3 using one of the European languages and then create an English user account with UserManager, when the new user logs in Workspace will use the language that you chose during installation, instead of English. The user can work around the issue by simply choosing the proper language in Preferences and then logging out and logging back in again. Note that new user accounts are only affected in this way if English is chosen when creating the user account.

NeXTSTEP 3.3 Patch 1 Release Notes Addendum

This document describes how to install the *NEXTSTEP Release 3.3 Patch Update* and describes the fixes contained in the update. This update is to be installed *only* on computers running *NEXTSTEP Release 3.3*.

For download and distribution information, see the **NeXTSTEP 3.3 Patch 1 Overview**.
This article has been archived and is no longer updated by Apple.

INSTALLING THE NEXTSTEP RELEASE 3.3 PATCH UPDATE

The *NEXTSTEP Release 3.3 Patch Update* consists of two User Patch packages:

3.3Intel68kPatch.pkg Contains updated system software for Intel PCs or NeXT computers running *NEXTSTEP Release 3.3*.

3.3HPPASPARCPatch.pkg Contains updated system software for Sun or HP workstations running *NEXTSTEP Release 3.3*.

and one Developer Patch package:

3.3DeveloperPatch.pkg Contains updated developer tools for all types of computers running *NEXTSTEP Developer Release 3.3*.

In addition, the *NEXTSTEP Release 3.3 Patch Update Floppy* contains:

3.3PatchRelNotesAddendum.rtfd This document.

Read-Me-First.rtfd A pointer to the installation instructions in this document.

3.3Patch.ImprovedDNS.post_install An installation script.

3.3Patch.LibrariesOK.post_install Another installation script.

Note the following points before you install the Patch Update packages:

Install just one package at a time. Install the User Patch package first; afterwards, install the Developer Patch package (if you're running *NEXTSTEP Developer Release 3.3*).

If you plan to use Emacs, be sure you've already installed the contents of the **Emacs.pkg** (contained on the *NEXTSTEP Release 3.3* CD-ROM) *before* installing the User Patch package.

When installing the Release 3.3 Patch Update packages, select the same architectures and languages as you did when originally installing the *NEXTSTEP Release 3.3* and *NEXTSTEP Developer Release 3.3* software.

After installing the Release 3.3 Patch Update packages, you must run one of the provided installation scripts. See the next section to decide which script you need to run.

Deciding which Installation Script to run

There are two installation scripts (**3.3Patch.ImprovedDNS.post_install** and **3.3Patch.LibrariesOK.post_install**) included with the *NEXTSTEP Release 3.3 Patch Update.* You need to run one of these scripts after installing the **3.3Intel68kPatch.pkg** or **3.3HPPASPARCPatch.pkg** Patch Update packages.

If you run any POSIX-based application on your system, or if you run any statically linked programs that uses the *gethostbyname()* or *gethostbyaddr()* system calls, you should run **3.3Patch.LibrariesOK.post_install**.

If neither of the above circumstances apply to your system, then you should run **3.3Patch.ImprovedDNS.post_install**.

Given the choice, **3.3Patch.ImprovedDNS.post_install** script is the better alternative. This option enables the changes to **lookupd** described later on in this document (Reference: 36740, 54181, 57737). Unfortunately, this optimization introduced an incompatibility with certain functions in the previously shipped static libraries, and you will be unable to fix this problem until a new set of static libraries is made available.

See the comments inside the scripts for details on what changes the scripts are making to your system.

Installing the NEXTSTEP Release 3.3 Patch Update Packages

Follow these instructions to install the *NEXTSTEP Release 3.3 Patch Update*.

1. Log in as **root**. (If you're not sure how to log in as **root**, see your system administrator.)

2. Make sure your computer is running *NEXTSTEP Release 3.3*. (You can find the NEXTSTEP version number with the Workspace Manager application's Info Panel command.)

Warning: Installing the *NEXTSTEP Release 3.3 Patch Update* on a computer that isn't running *NEXTSTEP Release 3.3* will result in unexpected problems. There is no way to remove the patch once installed. Your only recourse will be to reinstall NEXTSTEP.

3. Double-click the **3.3Intel68kPatch.pkg** file or the **3.3HPPASPARCPatch.pkg** file (be sure to choose the one that corresponds to the type of computer you're installing the package on).

4. Click the Install button in the Installer package window.
An Install Package panel opens. Use this panel to select the same architecture and languages as you did when originally installing the *NEXTSTEP Release 3.3* software.

5. Click Install in the Install Package panel, and if prompted for confirmation, click OK to proceed.
The Installer window displays information about the progress of the installation, which may take several minutes.

6. After Installer finishes installing the User Patch package (either **3.3Intel68kPatch.pkg** or **3.3HPPASPARCPatch.pkg**):

If you *haven't* previously installed *NEXTSTEP Developer Release 3.3* on the computer, go to Step 7.

If you *have* previously installed *NEXTSTEP Developer Release 3.3* on the computer, install the Developer Patch package by double-clicking the **3.3DeveloperPatch.pkg** file and repeating steps 4 and 5 (remember to select the same architectures as you did when originally installing the *NEXTSTEP Developer Release 3.3* software).

7. Run one of the two installation scripts on the *NEXTSTEP Release 3.3 Patch Update Floppy:*

Double-click on the **3.3Patch.ImprovedDNS.post_install** or **3.3Patch.LibrariesOK.post_install** file to run the script that you decided was appropriate for system.

8. you're donePlog out and restart the computer.

Installing the NEXTSTEP Release 3.3 Patch Update Packages

from a Network Server

If you're planning on installing the update packages from a Network Server onto multiple machines, you can simplify the operations to be performed somewhat:

1. Copy the installation packages (**3.3Intel68kPatch.pkg**, **3.3HPPASPARCPatch.pkg,** and **3.3DeveloperPatch.pkg)** to a file server location visible from all client machines that are to be upgraded.

2. Copy whichever of the installation scripts you're using (**3.3Patch.ImprovedDNS.post_install** or **3.3Patch.LibrariesOK.post_install**) to **<packagename>.post_install**, and move it into the base system update packages, as follows:

Copy (and rename) the appropriate script file to **3.3Intel68kPatch.post_install.**

Open the target package file by selecting it and pressing cmd-O**.**

Move the script file into the package directory. Close the directory window.

Do the same for the **3.3HPPASPARCPatch.post_install** file and the **3.3HPPASPARCPatch.pkg** directory.

3. Now, when you run the Installer application to install the update packages, the installation script will get executed automatically, and will not have to be run manually (skip step 7).

Addendum to the NEXTSTEP Release 3.3 Patch Update Release Notes

This addendum describes late-breaking information about the *NEXTSTEP Release 3.3 Patch Update*.

Problems Introduced in This Release

The following problems were introduced in this update:

Networking and Networking Tools

Reference: 36740, 54181, 57737
Problem: **lookupd** and DNS interaction add delays to many processes.
Comments: Our intended fix was to move the processing of DNS requests out of **lookupd** and into the calling command or application. We have since discovered a side effect of the fix included with the patch. Any comment lines in the **/etc/hosts** file would cause an additional search of all hosts defined in the NetInfo hierarchy. These extra searches could result in an unacceptable delay for all **lookupd** requests.

Fix #1: Add a **-R** option to the **lookupd** command in the **/etc/rc** file. This will force **lookupd** to use the old (pre-patch) behavior. This fix is implemented by the **3.3Patch.LibrariesOK.post_install** installation script.

Fix #2: Remove all comment lines from the **/etc/hosts** file. You can do this either manually with your favorite editor, or by using the following commands as root.
sed '/^#/d' /etc/hosts > /tmp/hosts
mv /tmp/hosts /etc/hosts
This fix is implemented by the **3.3Patch.ImprovedDNS.post_install** installation script.

Libraries

Reference: 59018
Problem: Patch does not include static libraries.
Comments: The *NEXTSTEP Release 3.3 Patch Update* does not include any new static libraries. This means that any programs that are linked with static libs can not benefit from fixes included with this release. In particular, if programs use the *gethostbyname()* or *gethostbyaddr()* library routines, and are statically linked, they must use Fix #1 for the **lookupd**

problem. Applications linked with the POSIX libraries are effected by this bug.

Problems NOT Fixed in This Release

The following problems have NOT been fixed in this update:

Networking and Networking Tools

Reference: 49580, 57746
Problem: NetInfo reconnecting does not prefer machines on the local subnet.
Comments: Our intentions were to correct the NetInfo binding and connecting strategy to select the server for a NetInfo domain by first checking on the local host, then on the local subnet, and finally on any accessible server host. We have since discovered that the reconnecting strategy will not "prefer" the local subnet when searching for a server. If a server crashes, clients connected to it won't take advantage of the new strategy when they reconnect. In these few cases, performance won't be improved but will be the same as in Release 3.3.

Problems Fixed in This Release

The following problems have been fixed in this update, but were not documented in the original release notes:

Libraries

Reference: 54336, 54033
Problem: sparc spin_lock() loops infinitely if multi-threading lock not acquired first time through
Fix: This sparc-specific bug has been fixed.

Miscellaneous Fixes

Reference: 52842, 56026
Problem: CERT Advisory: sendmail vulnerabilities.
Fix: The sendmail security vulnerabilities described in CERT Advisories CA-95:05 and CA-95:08 have been fixed. Contact CERT for more details.

Novell: How It Handles Desktop Information (11/94)

Does Novell duplicate the function of the Apple Desktop file or the Desktop Manager implementation on AppleShare?

What does the Resource Manager do when the desktop size exceeds the Resource Manager addressability limit?

This article has been archived and is no longer updated by Apple.
The AppleTalk Filing Protocol requires that each server maintain a desktop database containing information associating documents with applications and files with icons. This information helps the Finder know which icons to display for files, and which applications to launch when documents are opened. The Finder uses this database to build the familiar Macintosh graphical user interface.

In addition to a name, every Macintosh file has a four-character type code that identifies the nature of the file, and a four-character Creator code that identifies the application that created the file. For example, a document created by MacWrite has a Type value of WORD and a Creator value of MACA. The desktop database uses these values to find the appropriate icon for files of type WORD. Likewise, the desktop finds the appropriate application used for opening or printing files of this type using the value MACA.

When the Finder on a Macintosh workstation displays the contents of a server folder in a window, it attempts to find the appropriate icon for each file. First, the Finder looks in memory to see if it found the correct icon in a recent search. Then, it looks on the local Macintosh hard disk. If the icon is not found, the Finder requests the icon from the server. If the server volume's desktop database contains the appropriate icon, the server sends the icon to the Macintosh. If the icon is not found locally or in the server volume's desktop database, the Finder displays a generic icon for the file.

Once the Finder has determined that an icon cannot be found for a particular file type, it will not ask the server again until the Finder is restarted. This optimization prevents the Finder from repeatedly making the same request, which would slow the server.

In NetWare for Macintosh 4.0, the desktop database is stored in two files in the DESKTOP.AFP folder at the root of each volume. AFP.NLM creates the folder and database files on each volume that supports the Macintosh name space. These files, ICON.BTV and APPL.BTV, are in a proprietary, highly-optimized format, and are not meant to be used by programs other than AFP.NLM.

Maintaining and Rebuilding the Desktop Database

The Macintosh Finder and AFP.NLM share the responsibility of maintaining the desktop database. The Macintosh Finder incrementally updates the desktop database when it copies new files to the server volume. In version 7 and later, the Finder always ensures that when a document is copied to the server volume, the appropriate icons are also copied, if necessary. The Finder also updates the desktop database whenever it copies an application to the server volume, so that the application can be launched when documents are opened or printed.

NetWare for Macintosh is ultimately responsible for the contents and integrity of the desktop database for each of the volumes it supports. While it is possible to rebuild a server's desktop database using the System 6 Finder (but not MultiFinder), doing so will not enable you to locate the new color icons used in System 7. NetWare for Macintosh can examine all the files on each volume, and can rebuild the desktop database on each of its supported volumes. Because this process is carried out on the server, it is much faster and more efficient than rebuilding the desktop from a Macintosh workstation.

NetInstalling NeXTSTEP 3.3 With Additional Drivers

/etc/rc.cdrom is the rc file used during installation. A modifiedversion is available so that new drivers (i.e. released after 3.3 shipped) can be placed in an install image and installed on systems during a Net Install. This will keep the system from needing to ask for the driver floppy when it reboots during the installation. Also, if the new serial and serial mouse drivers are present, it will modify the Instance0.table to use them.

This article has been archived and is no longer updated by Apple.

The following assumes you have already set up a server for doing Net Installs. You can download the updated rc.cdrom file from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/rc.cdrom

1) In /NEXTSTEP_INSTALL/etc (the /etc directory in the Nextstep install image), rename rc.cdrom to rc.cdrom.orig.

2) Get NeXTanswer #2085 and rename it to rc.cdrom. Copy the new rc.cdrom script to /NEXTSTEP_INSTALL/etc.

3) Create a /NEXTSTEP_INSTALL/RELEASED_DRIVERS directory (/RELEASED_DRIVERS in the NEXTSTEP_INSTALL image).

4) Put the driver ***.pkg** packages in the /NEXTSTEP_INSTALL/RELEASED_DRIVERS directory.

DAL 1.2: Accessing VM Host Issue

1) I'm trying to get DAL 1.2 for VM to work with an IBM 3090. I'm using a Macintosh II connected by a coax, a DCA MacIrma card, and am running "DAL debugger for MacIrma".

After trying several times, I keep getting the error #10646 (-43). What does this error mean?

2) What state should the server be in when attempting access?

3) What programming languages support DAL development?
This article has been archived and is no longer updated by Apple.
1) Error -10646 means the DAL client cannot load the Network Adapter. You probably have the wrong driver installed. MacIrma is shipping with the HLLAPI drivers, which DAL doesn't support. You need to call DCA and get the Apple API drivers. Apple does not have the rights to distribute them, so you have to get them from DCA.

To verify this, the following files should be in the system folder:

DFT: "MacIrma SNA 2.1.0" (or .1) and "MacIrma DAL Driver" 1.2.0
CUT: "MacIrma DAL Driver" 1.2.0

In addition, be sure that your coax line is correctly identified as CUT or DFT in you DAL connention script.

2) Once a session is established between the DAL client and the DAL server, the server will be ready to accept any request from the client. Perhaps an explanation of DAL Request/Reply relationship would help:

DAL uses a request/reply relationship between the desktop and the server(s). The user connects to the host machine using the query tool (HyperCard, 4th Dimension, or a custom C or Pascal program). The query tool application passes the request to the DAL API, which in turn establishes a connection to the host server. The DAL server on the host receives the request and translates it to the SQL dialect of the opened database. The server then checks the syntax and passes the translated request to the proper database. The database complies and passes the data back to the DAL Host Server. The Host Server checks for errors, mapping them to the standard error set that DAL supports. The server then assembles the results returned from the database sends them to the Macintosh. The query application sees the results are available and begins to put them, item by item into its own window (such as a spreadsheet window).

3) DAL provides Application Programming Interfaces for C, Pascal, and HyperCard.

Macintosh: What is the Resource Manager?

This article has been archived and is no longer updated by Apple.
The Resource Manager, one of the cornerstones of Macintosh's ROM-based user Interface Toolbox, was designed and implemented by Bruce Horn, a member of the Macintosh software team. It provides a way for applications to separate their code from the data they use--to keep the data, such as prompt strings, menus or icons, in a separate, structured part of the file. This allows the data to be edited by a utility program without any specific knowledge of that application.

Since all of the language-dependent parts of an application are resources, an application may be translated to another language (French, German, etc.) in a matter of hours by a nontechnical translator without access to the source code. Similarly, users with this utility program can customize the prompts and phrases in an application to suit their particular tastes.

The Resource Manager has proven so useful that now many other parts of the system use it in one way or another. Desk accessories, code segment, fonts, icons, windows, menus, controls, and dialogs are all kept as resources.

DAL: Username and Password not Encrypted During Access (2/95)

When establishing a DAL session with a VAX over AppleTalk, is username and password information encrypted?

This article has been archived and is no longer updated by Apple.
The username and password information is not encrypted when sending to the host because AppleTalk does not encrypt. DAL does not furnish encryption, but uses whatever the network supplies.

NeXTSTEP 3.3 Driver: FTG ISA Light Pen

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated release version of this driver, version 3.30, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/released/FTGISALightPen.pkg.compressed

Driver Name / Installer .pkg: FTGISALightPen
Driver Type: Other
Driver Scope: Product Family
Supported Components: Custom
PC Bus / Interface Supported by Driver:** ISA
Supported Connectors: Custom
Access Mode: PIO
Adapter Memory: N/A

General Overview notes: This driver will support several FTG light pen models connected via an FTG PXL-395 ISA interface card. This driver may be used in conjunction with other pointing devices to allow the user to select the most convenient input device at any given time.

Supported Products / Add-on Adapters:
PXL-395 Light Pen Interface (ISA)
FT-356 1-Button Light Pen
FT-357 2-Button Light Pen

Supported Products / Systems (ie integrated into PC System):

NeXTSTEP 3.3 Driver: Trident Generic Display

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.30, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/TridentGeneric.pkg.compressed

Driver Name / Installer .pkg: TridentGenericDisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: Trident TGUI9440, Trident TGUI9680, Universal RAMDAC
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver will support a variety of video display devices based on Trident 9xxx chipsets.

NeXT does not guarantee that this driver will work with any specific adapters or implementations, but expects that it will support many.

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):
This driver will not support the built-in display on IBM Thinkpad 760CD.

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 2MB DRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1280x1024 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

Due to ongoing development and testing of OPENSTEP 4.0, the beta version (v3.30) of this driver will neither be tested on NEXTSTEP 3.3 nor upgraded to "Released" status.

Driver Version Notes

3.30 Original version, supports 9440 and 9680 based adapters.

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/Intel82557Net.pkg.compressed

Driver Name / Installer .pkg: Intel82557NetworkDriver
Driver Type: Networking
Driver Scope: Product Family
Supported Components: Intel i82557, Intel i82558
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver supports the Intel EtherExpress PRO/100+, PRO/100(model B), and the PRO/10+ PCI adapters. The PRO/100+ adapter used the 82558 ethernet controller, while the other two adapter families uses the 82557 controller.

Supported Products / Add-on Adapters:
Intel EtherExpress PRO/100+ PCI LAN Adapter (10Base-T, 100Base-TX)
Intel EtherExpress PRO/100 PCI LAN Adapter (PILA8465B) (10Base-T, 100Base-TX)
Intel EtherExpress PRO/100 PCI LAN Adapter (PILA8475B) (10Base-T, 100Base-T4)
Intel EtherExpress PRO/10+ PCI LAN Adapter (PILA8500) (BNC, AUI, RJ-45)
Intel EtherExpress PRO/10+ PCI LAN Adapter (PILA8520) (RJ-45)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:

Networking Driver Details

Network Type:** 100 Base T4, 100 Base TX, EtherNet, Full Duplex
Speed*: 10 Mb/s, 100 Mb/s
Access Mode:** Bus Master DMA
Buffer Size*: N/A
Supported Connectors:** AUI, BNC, UTP

Known Problems

Driver Version Notes

3.30 - Initial beta version
3.32 - Improved performance; added workaround for intermittent receiver errata to prevent hang
3.33 - Added support for Pro/10+ PCI adapter
3.36 - Added support for 82558 based adapters

libFoundation User Patch

The libFoundation User Patch provides fixes to several bugs introduced in NEXTSTEP Release 3.3 Foundation Library.

This patch is useful for several 3rd party products. These vendors should inform you if you do need this patch. If you have any question about which products, please contact the vendors of those products.

This is the same Foundation library that is included with EOF, NEXTSTEP 3.3J, and WebObjects (including the demo). If you have either of these installed, you do not need this patch.

Caution: These packages should only be installed on systems running NEXTSTEP Release 3.3.
This article has been archived and is no longer updated by Apple.
The *NEXTSTEP libFoundation User Patch Update* consists of one package:

FoundationUserPatch.pkg, available from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/patches/3.3/FoundationUserPatch.compressed

Contains updated shilb library for computers running *NEXTSTEP Release 3.3 and 3.3 patch 1*.

Installing the NEXTSTEP Release 3.3 Patch Update Packages

Follow these instructions to install the *libFoundation User Patch Update*.

1. Log in as **root**. (If you're not sure how to log in as **root**, see your system administrator.)

2. Make sure your computer is running *NEXTSTEP Release 3.3*. (You can find the NEXTSTEP version number with the Workspace Manager application's Info Panel command.)

Warning: Installing the *NEXTSTEP Release 3.3 Patch Update* on a computer that isn't running *NEXTSTEP Release 3.3* will result in unexpected problems.

3. Double-click the **FoundationUserPatch.pkg** file.

4. Click the Install button in the Installer package window.
An Install Package panel opens. Use this panel to select the same architecture and languages as you did when originally installing the *NEXTSTEP Release 3.3* software.

5. Click Install in the Install Package panel, and if prompted for confirmation, click OK to proceed.
The Installer window displays information about the progress of the installation, which may take several minutes.

6. After Installer finishes installing the User Patch package log out and restart the computer.

Driver Name / Installer .pkg: Number9Motion331DisplayDriver
Driver Type: Display
Driver Scope: Specific Product
Supported Components: S3 764 (Trio64V+)
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver supports both 1MB & 2MB versions of the Number Nine MotionFX 331 display adapter.

Supported Products / Add-on Adapters:
Number Nine 9FX Motion 331 1MB PCI (NB9-FX1-331-1P)
Number Nine 9FX Motion 331 2MB PCI (NB9-FX1-331-2P)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This adapter is not recommended for applications requiring 32 bit color; 32 bit modes will appear dim because the hardware does not implement gamma correction.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 2MB DRAM

WebObjects 3.5.1 Development FAQ

This article contains frequently asked questions (FAQ) regarding WebObjects 3.5.1 Development, with answers to those questions.
This article has been archived and is no longer updated by Apple.
Questions answered in this article:

1. Can I implement my WO bundles in some sort of hierarchy?
2. Is the NS-API version of the WebObjects adaptor available for both Solaris and Windows NT versions of the Netscape server?

Question 1: Can I implement my WO bundles in some sort of hierarchy?

Answer: WebObjects searches for a reusable component in these places and in this order:

1. The directory in which the WebObjects app executable is (only useful if that executable is in a .app or .debug, i.e. with Pro or Enterprise),

2. The app's directory under the WebObjects document root,

3. The WebObjects document root, <HTTPDocumentRoot>/WebObjects (this was meant as a way to share .wo's across different apps, but a more practical way to do that is to put the shared .wo's in a separate directory somewhere and symlink them to different apps' directories).

Question 2: Is the NS-API version of the WebObjects adaptor available for both Solaris and Windows NT versions of the Netscape server?

Answer: Yes, both are included with the Pro and Enterprise versions of WebObjects. The source for the CGI and the NSAPI adaptors are on the CD.

PATHWORKS: Printing on AppleTalk Phase 1 Networks

We are implementing the Tolas accounting system using PATHWORKS for Macintosh. We will be linking a MicroVAX to Macintoshe systems on Ethernet and using LocalTalk to connect to our LaserWriters. Since we are using AppleTalk Phase 1, we can't send files to the LaserWriters.

Can we do what we want without using PATHWORKS for Macintosh? Can we just run AppleTalk for VMS 3.0 and still support AppleTalk Phase 1?

This article has been archived and is no longer updated by Apple.

PATHWORKS for Macintosh is the name for an integrated set of components in one client/server product. The package includes file sharing, data access, electronic mail, and resource services for Macintosh clients. AppleTalk for VMS 3.0 is included in the product but it supports only AppleTalk Phase 2.

If you are using the Apple Internet Router, install the Upgrade Utility. If you are using non-Apple routers, use an equivalent Phase 1/Phase 2 transition utility. Because this is only a temporary solution, eventually you will want to upgrade all your routers to AppleTalk Phase 2.

Consult the AppleTalk Phase 2 Introduction and Upgrade Guide for upgrade procedures.

Pentium Pro Performance under NeXTSTEP

Question

I have heard that there are performance problems with Pentium Pro systems due to the "Orion" chipset. Is NEXTSTEP effected by this problem?

This article has been archived and is no longer updated by Apple.

Answer

Some Pentium Pro systems have extremely poor PCI bandwidth. This directly translates to reduced video performance under NEXTSTEP. Machines built with the latest Intel chipset probably will not exhibit this problem.

Some customers have reported poor performance of NEXTSTEP on some Pentium Pro systems. The NeXT SQA department has performed some benchmark tests and determined that these problems are most likely the result of the PCI bandwidth problem with the first version of Intel's "Orion" support chip set. An Intel prototype system with the "B0" stepping of the Orion chipset performs as expected (i.e. really, really fast) under NEXTSTEP.

The following is an excerpt from an Intel press release:
"The Orion chipset, known internally as 82450, is one of a number of auxiliary chips that supplies the Pentium Pro microprocessor. An uncorrected chipset could limit the amount of so-called I/O bus traffic, or data transfer, that a computer handles to as low as five megabytes per second, instead of the regular 25 to 55 megabytes, said Intel spokesman Howard High."

VAX RDBMS: Access from Macintosh and MS-DOS

Is there an RDBMS for VAX/VMS that fully uses the Macintosh as a VAX server client? Most RDBMS packages only use the Macintosh in VT100 emulation mode. I want a package that gives the Macintosh and PC the same screen look.
This article has been archived and is no longer updated by Apple.
Check the following Client/Server VAX database access products:

* Apple's Data Access Language (DAL):

An Apple DAL Server can run on VAX/VMS providing Data Access Language access to databases. The server works cooperatively with Macintosh applications that support Data Access Language.

The server receives a request from a Macintosh application, carries it out on the VAX, and sends the desired data back to the Macintosh application. The Macintosh application can be HyperCard, 4th Dimension, popular spreadsheet products such as Excel and WingZ, or C programs. DAL operates under existing host and database-management security and integrity schemes, assuring complete data security with no additional maintenance requirements.

The server supports serial lines (directly or via modem) or AppleTalk Data Stream Protocol (requires Apple's AppleTalk for VMS running on VAX system). Databases supported by DAL Server for VAX/VMS include: Informix, Ingres, Oracle, VAX Rdb/VMS, and Sybase.

Apple DAL Server is available from APDA.

* SequeLink, Version 2.1:

This program allows cooperative processing between Macintosh and VAX computers. With it, you can write a Macintosh front-end to a relational database residing on a VAX, using environments such as HyperCard, Microsoft Excel or 4th Dimension, and compiled languages such as C, Pascal, or MacApp. Your Macintosh application can then access transparently the relational database on the VAX, off-loading the VAX.

SequeLink can write on-line transaction processing application and decision support applications. SequeLink supports Oracle, Ingres, VAX Rdb/VMS, and Sybase. It runs over AppleTalk and DECnet. The SequeLink product family includes other client and server platforms, such as MS-DOS, OS/2, UNIX, AS/400, and MVS.

SequeLink, Version 2.1 is available from TechGnosis, Inc.

PATHWORKS: VAXshare Support for LaserWriter 6.0.X

How do I get VAXshare Print Service in PATHWORKS for Macintosh to work with LaserWriter 6.0.X? The help facility in PATHWORKS doesn't help.

This article has been archived and is no longer updated by Apple.

There are two modules in the device control library that are not only unnecessary, their presence prevents the ADD PRINTER command from working correctly. Delete them with this command:

```
$ library/delete=(msap$permdict1,msap$permdictquery1) -
_$ sys$library:msap$devctl.tlb
```

Then, add the printer, using the /SETUP qualifier to specify the appropriate level of Laser Prep (msap$appledict70 = Laser Prep 6.0):

```
MSA$MANAGER> add printer "Spooler Name" -
_MSA$MANAGER> /queue=sys$print -
_MSA$MANAGER> /destination="Printer Name@Zone Name" -
_MSA$MANAGER> /setup=msap$appledict70
MSA$MANAGER> start printer "Spooler Name"
```

Other modules available in the device control library are:

MSAP$APPLEDICT66 (Laser Prep 5.0)
MSAP$APPLEDICT67 (Laser Prep 5.1)
MSAP$APPLEDICT68 (Laser Prep 5.2)

If /SETUP is not used, the default is 5.2.

Macintosh IIsi, LC Series: Not Designed for Vertical Operation

Article Change History

07/12/93 - REVISED
* To include Performa 400 series.
02/01/93 - REVISED
* To include the LC III.

I want to use my Macintosh IIsi and Macintosh LC in a vertical position. If I leave enough room for ventilation, will this cause any problems?

This article has been archived and is no longer updated by Apple.
The Macintosh IIsi, the Macintosh LC Family (LC, LC II, LC III), and Performa 400 series (Performa 400, 405, 430, 450) weren't designed to operate on their sides. Because Apple hasn't tested these computers in a vertical position, Apple can't recommend that customers use them this way.

We do know that the floppy-disk drives and hard drives will work properly either horizontally or vertically. Ventilation shouldn't be a problem as long as there's 4 to 6 inches of clearance around all the computer's vents.

General Overview notes: This driver supports the 3COM EtherLink III Ethernet Adapter.

Supported Products / Add-on Adapters:
3Com EtherLink III 3C509 ISA (BNC, AUI)
3Com EtherLink III 3C509B ISA (BNC, AUI)
3Com EtherLink III 3C509-TP ISA (RJ-45, AUI)
3Com EtherLink III 3C509B-TP ISA (RJ-45, AUI)
3Com EtherLink III 3C509-COMBO ISA (BNC, AUI, RJ-45)
3Com EtherLink III 3C509B-COMBO ISA (BNC, AUI, RJ-45)
3Com EtherLink III 3C509-TPO ISA (RJ-45)
3Com EtherLink III 3C509B-TPO ISA (RJ-45)
3Com EtherLink III 3C579 EISA (BNC, AUI)
3Com EtherLink III 3C579-TP EISA (AUI, RJ-45)
3Com EtherLink III 3C589C-COMBO (BNC, RJ-45)
3Com EtherLink III 3C589C-TP (RJ-45)

Networking Driver Details

Network Type:** EtherNet
Speed*: 10 Mb/s
Access Mode:** Memory Mapped
Buffer Size*: 8KB
Supported Connectors:** AUI, BNC (10Base-2), RJ-45 (10Base-T)

Driver Version Notes

3.31 Significant performance improvements; added support for the 3C589 PC Card (PCMCIA) adapter - Requires version 3.34 or later of the PCMCIABus driver
4.01 - Released on OPENSTEP 4.0 User CD-ROM

NeXTSTEP 3.3 Driver: S3 ViRGE Display

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.30, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/S3ViRGEDisplay.pkg.compressed

Driver Name / Installer .pkg: S3ViRGEDisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: S3 325 (ViRGE)
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver supports the Number Nine Reality 332 and Diamond Stealth 3D 2000 display adapters. Other S3 ViRGE implementations that adhere to S3's reference BIOS should be supported as well.

Supported Products / Add-on Adapters:
Number Nine 9FX Reality 332 PCI Display Adapter
(90-332010-000, 91-332010-000, 91-332013-000)
Diamond Stealth 3D 2000 PCI Display Adapter

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
The 1152x864 modes listed below are supported only by the Number9 Reality 332 Display Adapter. These modes are not available on the Diamond Stealth 3D 2000, and are not supported on generic S3/ViRGE implementations.

This adapter is not recommended for applications requiring 32 bit color; 32 bit modes will appear dim because the hardware does not implement gamma correction.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB EDO DRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 1152x864 (2MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

AppleShare PC: Using with Extended Memory (11/94)

I want to load parts of PhoneNet Talk software into extended memory. I also want to load AppleShare Print Server and File Server into the top 3MB of expanded memory on a 4MB 386 machine. I'll be running PFS FirstChoice and the QEMM-386 utility.

Can I do this? How?

This article has been archived and is no longer updated by Apple.
Yes, most of AppleShare PC can be loaded into a PC's "high memory" (conventional memory is the range from 0 to 640K, high memory is the range between 640K and 1024K). High memory is generally used by the PC BIOS, expansion cards, video memory, and other system resources. Very few PCs use their entire address range for such purposes. Most machines have space available that can be mapped to extended memory and used to load user software, such as drivers and TSR (Terminate and Stay Resident) utilities.

Unfortunately, DOS doesn't have a standard way to manage high memory ranges for user programs. It also can't find available ranges within high memory. Using this space means that programs sharing the same memory space may begin to write over each other resulting in unpredictable crashes, freezes, and generally weird behavior.

The QEMM-386 utility addresses this problem by providing extended, expanded, and high memory management functions. Extended and expanded memory is beyond the scope of this discussion and is somewhat irrelevant to your problem. What you should be concerned about is high memory.

QEMM-386 maps out available high memory ranges. Once this is done, QEMM-386 can then begin to "LOADHI" specific software, usually drivers and TSR utilities.

This whole process is a bit involved but is documented well in the QEMM-386 manuals. We strongly recommend that you read it. Below is a rough outline of the procedure. This general procedure must adapt to fit the needs of the specific hardware and software you're using.

1) Install AppleShare PC, and confirm it functions satisfactorily, allowing it to load from the AUTOEXEC.BAT file.

2) Perform a basic install of QEMM-386. Modify its line in the CONFIG.SYS file, enabling its "ON" option. Reboot. QEMM-386 and AppleShare PC should both load.

3) Exercise the installed hardware, meaning format floppy disks, print something, send something through each COM port, and so forth. The idea is to access memory ranges that may be associated with the PC hardware.

4) Without rebooting, use the QEMM analysis feature to determine which high memory ranges are available and which are already in use by the PC.

5) Modify the CONFIG.SYS line for QEMM-386 to INCLUDE and EXCLUDE the appropriate memory ranges discovered in the previous step. Also, remove the ON option you added in step 2. Reboot.

6) Use the QEMM-386 Optimize program to find which parts of the system and AppleShare PC it can load into the new high memory. This is a fairly automated process, but it requires three reboots. When complete, the Optimize program should indicate how much conventional memory was saved by loading software into high memory instead of conventional memory.

7) Confirm that the MINSES.EXE program is not one of those that is loaded into high memory. If it is, change it by removing the reference to LOADHI that loaded it. MINSES is a required part of the AppleShare PC software, but will cause problems if loaded into high memory. (MINSES and REDIR were both written by Microsoft, and assist in directing standard DOS commands to network devices.)

This is a very short description of the process, but it should give you a general idea of what to do. Again, we recommend reading the QEMM-386 manual for exact details. In addition to installation, the manual covers the different capabilities and uses for each PC memory type.

Adaptec 154x Family and Compatible OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Adaptec 154x family and compatible
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CDROM
An updated release version of this driver, version 4.01, is available on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/Adaptec1542B.pkg.compressed

Driver Name / Installer .pkg: Adaptec1542B
Driver Type: SCSI
Driver Scope: Product Family
Supported Components: Adaptec AIC-6251, Adaptec AIC-7970
PC Bus / Interface Supported by Driver:** EISA, ISA

General Overview notes: The Adaptec154x compatible driver is designed to support a variety of SCSI adapters from Adaptec and several third parties.

Supported Products / Add-on Adapters:
Adaptec 154xB (ISA)
Adaptec 154xC (ISA)
Adaptec 154xCF (ISA)
Adaptec 1542CP (ISA Plug and Play)
Adaptec 174x (EISA) in standard 154x mode only

Special Features of Driver / Driver Notes:
The onboard floppy controller, available on the 1542 cards, is not supported.

SCSI Driver Details

Supported Connectors: 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2)
Access Mode: DMA
Attributes:** SCSI-2
Cache Size Supported:** N/A

Known Problems

· For setup and installtion of the 154xB see
NeXTanswers document number 1107.

· For setup and installtion of the 154xC/CF see
NeXTanswers document number 1108.

· NEXTSTEP does not officially support the floppy controller integrated into the 1542B. Use the floppy controller integrated into your system's motherboard.

· When installing NEXTSTEP onto an IDE hard disk drive, the CD-ROM drive's SCSI ID number should be zero.

· Some users have reported problems during the installation process if the CD-ROM drive's SCSI ID number is set to zero. NEXTSTEP will freeze after displaying the message rootdev 608 when this problem is encountered. Setting the CD-ROM drive's SCSI ID to six has fixed the problem when nothing else seemed to work.

· Improper SCSI termination can cause strange, unreproducible errors. Be certain that the first and last devices on the SCSI bus (and only these two devices) are terminated.

· Avoid system configurations combining an Adaptec 154xB/C/CF and an ATI Ultra Pro EISA card. A hardware conflict exists which causes data corruption on SCSI hard disks.

· If your system includes an Adaptec 1542B and you do not have jumper six enabled it will hang. It will boot off the floppy and recognize the SCSI drives, but instead of starting the install process, it will hang with the messages:

fdisk: bogus bios info
some bios' can't handle non-sequential targets.

· The Adaptec 1542B does not support 2.88MB floppy drives attached as SCSI devices.

Driver Version Notes

4.00 Released on OPENSTEP 4.0 User CD-ROM
4.01 Added support for 1542CP Plug and Play adapter.

Adaptec 274x and 284x SCSI Adaptor OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Adaptec 274x and 284x family
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: Adaptec2740
Driver Type: SCSI
Driver Scope: Product Family
Supported Components: Adaptec AIC-7770
PC Bus / Interface Supported by Driver*: EISA, VL-Bus

General Overview notes: The Adaptec 274x series driver is designed to support the 274x series of EISA SCSI adapters and the 284x series of VL-Bus SCSI adapters. The 2(7,8)42 versions include a floppy controller.

Supported Products / Add-on Adapters:
Adaptec 2740 (EISA) - not tested but should work
Adaptec 2740T (EISA)
Adaptec 2840 (VLB)

Special Features of Driver / Driver Notes:
The 274x is available in a 'T' version that includes two SCSI channels, both channels are supported by this driver.

The onboard floppy controller available on the 2(7,8)42 cards is not supported.

SCSI Driver Details

Supported Connectors: 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2), 68-pin High Density (Wide SCSI)
Access Mode: DMA
Attributes:** SCSI-2
Cache Size Supported:** N/A

Known Problems

The 284x driver uses port 4c00 by default. You must set the DIP switches on your 284x card to use this port. The correct settings are:
sw1:on
sw2:on
sw3:off
sw4:off

The 274x driver uses port 0x4c88 by default.

PATHWORKS VAXshare: Multilaunching Applications (11/94)

I'm testing PATHWORKS for Macintosh and have a problem multilaunching Claris applications, such as MacDraw, on the VAX. I'm able to multilaunch Microsoft applications on the VAX.

Is this only a problem with Claris? Is there a way to fix this?

Ideally, I'd like to be able to share all the applications on the VAX between the Macintosh users.

This article has been archived and is no longer updated by Apple.
This situation isn't just limited to a PATHWORKS VAXshare server. We tried the same thing on an AppleShare File Server and got the same result.

Microsoft Technical Support says that Microsoft Word, Microsoft Excel, Microsoft File, and PowerPointare all multilaunch applications. Each has some limited multi-user capabilities as well.

This is not a limitation of Claris' software: these applications are not supported as multilaunch applications. The effects of multilaunching are unknown. Also, keep in mind possible licensing problems, because these applications are sold as single-user applications.

Check with the vendor of the application to determine if it provides multi-launch capability.

OPENSTEP 4.x Driver: Adaptec 2940 and 7870 SCSI

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.

NOTE: Apple Enterprise Software has suspended on-going development of new drivers for the NeXTSTEP and OPENSTEP product lines. Where possible, we will be updating current drivers for minor product revisions. These drivers will be made available in the TIL.

For a complete list of supported drivers for the OPENSTEP operating system, see the **OPENSTEP Driver Compatibility Guide**.
This article has been archived and is no longer updated by Apple.

Availability Information

A version of this driver is on the OPENSTEP CD-ROM

An updated release version of this driver, version 4.03, is avaiable on Apple's FTP servers at:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/Adaptec2940SCSI.pkg.compressed

Driver Name / Installer .pkg: Adaptec2940SCSIDriver

Driver Type: SCSI

Driver Scope: Product Family

Supported Components: Adaptec AIC-7850, Adaptec AIC-7870, Adaptec AIC-7870D, Adaptec AIC-7880

PC Bus / Interface Supported by Driver*: Integrated, PCI

General Overview notes:

The Adaptec 2940 series driver is designed to support the 2940 series of PCI SCSI adapters. A driver for Adaptec 7895 and other drivers, see the Adaptec 78xx Driver Overview, **TIL article 70011**.

Supported Products / Add-on Adapters:

Adaptec AHA-2930B (PCI)

Adaptec AHA-2940 (PCI)

Adaptec AHA-2940W (PCI, Wide SCSI)

Adaptec AHA-2940U (PCI, Ultra SCSI)

Adaptec AHA-2940UW (PCI, Ultra/Wide SCSI)

Adaptec AHA-2910B (PCI) - Not tested but should work.

Supported Products / Systems (ie integrated into PC System):

DEC EISA/PCI Server system w/ 7870 on motherboard

DEC Celebris GLST w/ 7850 on riserboard

HP Kayak on-board 7860 & 7880 based SCSI adapters.

Special Features of Driver / Driver Notes:

This driver does not support the Adaptec AHA-2920 (PCI)

SCSI Driver Details

Supported Connectors: 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2), 68-pin High Density (Wide SCSI)

Access Mode: Bus Master DMA

Attributes*: SCSI-2

Cache Size Supported*: N/A

Known Problems

The Adaptec 2940 SCSI Host Adapter Driver supports Synchronous Data Transfer as well as Fast SCSI transfers. In order to enable Synchronous Data Transfer, this feature must be enabled in both the 2940's AutoSCSI program and in the NEXTSTEP Configure application, when configuring the Adaptec 2940 driver. In the AutoSCSI program, this feature is enabled in the SCSI Device Configuration menu, via the Initiate Sync Negotiation field. This can be enabled or disabled on a per-target basis. In the Configure application, the Synchronous button, if disabled, disables Synchronous Transfers for ALL targets. If enabled, the values selected in the AutoSCSI program are used to determine whether or not Synchronous Transfers occur on a per-target basis.

The Synchronous Transfer data rate is determined in the 2940's AutoSCSI program, via the Maximum Sync Transfer Rate field in the SCSI Device Configuration menu. Fast SCSI Transfers are enabled by selecting a value of 10 (i.e., 10 Megabytes/seconds) for this field. Note that if Synchronous Transfers are disabled, the Maximum Sync Transfer Rate field is meaningless. Also note that it is not recommended to select a value higher than 5 for a device which is in an external enclosure and connected to the 2940 via an external SCSI cable.

Driver Version Notes

3.33 - Added support for Adaptec's AIC-7850 chipset.

3.36 - Added support for Adaptec's AIC-7870 revision D (needed to support the latest revisions of the AHA2940 & AHA2940W)

3.37 - Integrate Adaptec's HIM v1.21 to support the AHA2940U & AHA2940UW Ultra SCSI host adapters.

4.00 - Released on OPENSTEP 4.0 User CD-ROM

4.02 - Fixes a bug which prevented adapters with BIOS rev. 1.32 from working on machines with Phoenix BIOS

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

Driver Name / Installer .pkg: AIC6X60SCSI
Driver Type: SCSI
Driver Scope: Generic-Chipset
Supported Components: Adaptec AIC-6360
PC Bus / Interface Supported by Driver*: Integrated, ISA

General Overview notes: The Adaptec 6x60 Compatible SCSI driver is designed to support a variety of SCSI adapters which incorporate the Adaptec 6260 & 6360 SCSI controller chipsets.

Supported Products / Add-on Adapters:
Adaptec AVA-1505A (ISA)
Adaptec AVA-1515A (ISA)
Adaptec AHA-1520A (ISA)
Adaptec AHA-1530P (ISA) - Not tested but might work.
Adaptec Slim SCSI (PC/MCIA)

Supported Products / Systems (ie integrated into PC System):
Intel GX/Pro

Special Features of Driver / Driver Notes:
The onboard floppy controller, available on some cards, is not supported.

SCSI Driver Details

Supported Connectors: 25-pin DB25 (Mac SCSI), 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI), 50-pin High Density (SCSI-2)
Access Mode: PIO
Attributes*: SCSI-2
Cache Size Supported*: N/A

Known Problems

Never tested with Compaq Portable 486/M,C and does not work.
Next SCSI color printer currently does not work with the Adaptec 6x60 driver.

Driver Version Notes

3.32 - Adds support for Adaptec Slim SCSI (PC/MCIA) and SoundBlaster 16 integrated SCSI.
4.00 - Released on OPENSTEP 4.0 User CD-ROM

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

Driver Name / Installer .pkg: AMDPCSCSIDriver
Driver Type: SCSI
Driver Scope: Generic-Chipset
Supported Components: AMD Am53C974, AMD Am79C974
PC Bus / Interface Supported by Driver:** Integrated, PCI

General Overview notes: This driver should support the AMD Am53C974 family of PCI SCSI controllers. The 79C974 is a combo chip with contains an Am79C970 ethernet core and an Am53C974 SCSI core

Supported Products / Add-on Adapters:
The AMDPCSCSI driver is known to work with the following SCSI devices:
Toshiba CD-ROM XM-3401T
Peripheral Solutions 8mm Exabyte DAT Drive -- 8500
Syquest 88MB SQ5110 D3G 810
IOMEGA Bernoulli 230 BETA230 1.1408/2

AMD PCnet32 Network Adaptor OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: AMD PCnet32
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: AMDPCnet32NetworkDriver
Driver Type: Networking
Driver Scope: Generic-Chipset
Supported Components: AMD Am79C965, AMD Am79C970, AMD Am79C974
PC Bus / Interface Supported by Driver:** Integrated, PCI, VL-Bus

General Overview notes: This driver is designed to support LAN adapters that use the AMDPCnet32 ethernet controller. The AMD PCnet32 Ethernet controller is used in both integrated designs (on-board system boards or accessory daughter cards) and add-on VL-Bus and PCI adapters. This OPENSTEP driver is designed to support generic implementations of the AMD Am79C965 and Am79C970 chipset (ie designs that follow the example design as provided by AMD). The 79C974 is a combo chip with contains an Am79C970 ethernet core and an Am53C974 SCSI core

Supported Products / Add-on Adapters:
X/Lan Add-On Adapter (based on Am79C970)

Supported Products / Systems (ie integrated into PC System):
Canon object.station 41
Compaq Deskpro XL (On-board)
HP Vectra XU (On-Board)

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Networking Driver Details

Network Type*: EtherNet
Speed*: 10 Mb/s
Access Mode*: Bus Master DMA
Buffer Size*: N/A
Supported Connectors*: AUI, UTP

Known Problems

Due to reliability issues, it is not recommended that you use the this driver with HP Vectra XU machines.

IBM PCI Ethernet Adapter (based on Am79C970, IBM part #13H9237) is reported to work but has not been tested by SQA.

Driver Version Notes

3.33 - Added support for an updated version of PCnet32 PCI hardware.
4.00 - Released on OPENSTEP 4.0 User CD-ROM

ATI Display OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: ATI
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: ATI
Driver Type: Display
Driver Scope: Product Family
Supported Components: AT&T ATT20C491 RAMDAC, ATI 68800 (Mach32), ATI 68830 RAMDAC, ATI 68875 RAMDAC, Brooktree Bt481 RAMDAC, Brooktree Bt485 RAMDAC
PC Bus / Interface Supported by Driver*: EISA, Integrated, VL-Bus

General Overview notes: This driver is obsolete and has been replaced by ATIMach32.

The ATI graphics driver is designed to support the ATI 68800 graphics controller (also known as Graphics Ultra Pro or Mach 32). Although ATI makes a broad range of graphics controllers, only the 68800 supports the linear frame buffer mode required by NEXTSTEP for 32-bit,16-bit color or 8-bit grayscale. This driver supports EISA, custom LocalBus and VESA LocalBus versions of 68800 graphics adapters. This driver also supports a variety of RAMDAC's used with these chips. Although ATI has set some standards for choice of RAMDAC, this driver should only be expected to work with the specific systems and adapters listed. Note: ATI is in the process of updating the 68800 from Rev 3 to Rev 6A. Although the Rev 6A chip is designed to be compatible with Rev 3 drivers, this driver update will be tested with Rev 3 and Rev 6A chips.

Supported Products / Add-on Adapters:
ATI Graphics Ultra Pro (EISA, ATI 68875 RAMDAC)
ATI Graphics Ultra Pro (EISA, TI 34075 RAMDAC)
ATI Graphics Ultra Pro (VL-Bus, ATI 68875 RAMDAC)

Supported Products / Systems (ie integrated into PC System):
Intel GX/Pro (Custom LB, onboard ATI, TI 34075 RAMDAC)
Data General Dasher DE2 (Custom LB, TI 34075 RAMDAC)
AST Premmia 4D (Custom LB, onboard ATI, BT 481 RAMDAC)
Gateway V Series (VL-Bus, ATI 68875 RAMDAC)

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB VRAM, 2MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:

16 Bit Color Modes*:
1024x768 (2MB+), 1120x832 (2MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1120x832 (1MB+), 1280x1024 (2MB+), 800x600 (1MB+)

Known Problems

The ATI Ultra Pro driver reserves a large number of I/O ports to accomodate SoftPC in full-screen mode. Some of these ranges may conflict with other drivers. In particular, the range 0x52eee-0xfeef may be a problem. This conflict can be resolved simply by removing this reserved range from the driver configuration. Note, however, that this may prevent SoftPC from running correctly in full screen mode. The procedure to remove the port range is as follows:
- run Configure.app and select the display driver
- select the Expert options for the driver
- find the I/O Ports entry and double-click on the values to edit them
- scroll the field all the way to the right and delete the range 0x52ee-0xfeef. Make sure to hit return after editing, or the change won't be made.
- save the configuration and reboot

ATI Mach32 Display OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: ATI Mach32
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: ATIMach32
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: AT&T ATT20C491 RAMDAC, ATI 68800 (Mach32), ATI 68830 RAMDAC, ATI 68875 RAMDAC, Brooktree Bt481 RAMDAC, Brooktree Bt485 RAMDAC
PC Bus / Interface Supported by Driver*: EISA, Integrated, PCI, VL-Bus

General Overview notes: Generic Driver for the ATI Mach32 (Also known as 68800) Rev 3, Rev 6 and AX.

Supported Products / Add-on Adapters:
ATI Graphics Ultra Pro - EISA (with 2MB VRAM)
ATI Graphics Ultra Pro - PCI (with 2MB VRAM)
ATI Graphics Ultra Pro - VL-Bus (with 2MB VRAM)
ATI Graphics Ultra Pro XLR - VL-Bus (with 2MB DRAM) - not tested, but should work
ATI Graphics Ultra Pro XLR - PCI (with 2MB DRAM) - not tested, but should work

Supported Products / Systems (ie integrated into PC System):
Intel GX/Pro (Custom LocalBus, onboard ATI, TI 34075 RAMDAC)
Data General Dasher DE2 (Custom LocalBus, TI 34075 RAMDAC)
AST Premmia 4D (Custom LocalBus, onboard ATI, BT 481 RAMDAC)
Gateway V Series (VESA LocalBus, ATI 68875 RAMDAC)

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 1MB VRAM, 2MB DRAM, 2MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:

16 Bit Color Modes*:
1024x768 (2MB+), 1120x832 (2MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1120x832 (1MB+), 1280x1024 (2MB+), 800x600 (1MB+)

Known Problems

NeXT SQA has experienced some display problems with the ATI Mach32 VL-Bus adapter on machines using the OPTi chip-set. One of the problems is the machine will hang in any of the 8-bit greyscale display modes. However, machines without this chip-set behave normally.

NeXT SQA has witnessed some video noise in 800x600 display modes for adapters with the 68003 Mach32 chip.

ATI Mach64 OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: ATI Mach64
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: ATIMach64DisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: ATI 88800 (Mach64)
PC Bus / Interface Supported by Driver*: Integrated, PCI, VL-Bus

General Overview notes: This new graphics driver is designed to support a variety of graphics adapters using the ATI 88800 graphics controller. Adapters based on the 88800 GX/CX (also known as the Mach64) graphics controller chipset can support 1MB, 2MB or 4 MB of VRAM or DRAM. This driver supports a variety of configurations including high-resolution and high-color (32bit) modes and several RAMDAC, frame buffer and interface bus (PCI and VL-Bus only) configurations.

Due to the wide range of possible combinations, only a few specific adapters will be tested by NeXT. Although this driver may work with most 88800 GX/CX based adapters, Apple will only support the specific adapters tested by Apple.

Supported Products / Add-on Adapters:
ATI Graphics Ultra Pro Turbo (PCI, with 2MB VRAM)
ATI Graphics Ultra Pro Turbo (PCI, with 2MB DRAM)
ATI Graphics Ultra Pro Turbo (PCI, with 4MB VRAM)
ATI Graphics Ultra Pro Turbo (PCI, with 4MB DRAM)
ATI Graphics Ultra Pro Turbo (VL-Bus, with 4MB VRAM)
ATI Graphics Ultra Pro Turbo (VL-Bus, with 4MB DRAM)

Supported Products / Systems (ie integrated into PC System):
AT&T Globalyst 600

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB DRAM, 2MB VRAM, 4MB DRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
640x480 (4MB+), 800x600 (4MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1152x896 (2MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1152x896 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 800x600 (1MB+)

Known Problems

The Mach64 driver makes use of the board's BIOS to switch modes. This requires the user to set up the display adapter as specified in the documentation supplied by ATI. This will usually require running a setup utility. Until this is done, not all supported display modes will be available.

Driver Version Notes

3.33 - Added support for additional hardware
3.34 - Added support for ATI 68860 Rev C and ST1703 RAMDACs.
3.36 - Beta - Driver rewritten to call Adapter's BIOS to switch modes.
3.37 - First Released version that uses the Adapter's BIOS - should be robust to RAMDAC changes.
4.01 - Released on OPENSTEP 4.0 User CD-ROM

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

Driver Scope: Specific Product
Supported Components: BusLogic BA81C15
PC Bus / Interface Supported by Driver*: PCI

General Overview notes: The BusLogic FlashPoint SCSI driver is designed to support the KT-930 SCSI adapter from BusLogic.

Supported Products / Add-on Adapters:
BusLogic KT-930 PCI SCSI Host Adapter
BusLogic KT-932 PCI Dual Chanel SCSI Host Adapter
BusLogic BT-950 PCI Wide SCSI Host Adapter

BusLogic Family SCSI Adaptor OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: BusLogic family
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: BusLogicSCSIDriver
Driver Type: SCSI
Driver Scope: Product Family
Supported Components: BusLogic BA90C30
PC Bus / Interface Supported by Driver*: EISA, ISA, PCI, VL-Bus

General Overview notes: The BusLogic SCSI driver is designed to support the 747C and 445C series SCSI adapters from BusLogic. This driver is specifically designed to support the 32bit extended modes supported by these adapters. In comparison to the Adaptec 154x compatible mode previously used to support the 747S and 445S adapters, these extended modes provide additional performance, and remove the double buffering required by the16MB address limitation. This driver may work with other versions of BusLogic SCSI adapters such as the 545C, 747S and 445S. Since these adapters are supported in Adaptec compatibility mode with the existing Adaptec 154x driver, this driver will only be tested and supported on the latest generation, higher performance 747C and 445C series adapters. Note: In general this driver was designed to work with any BusLogic bus master SCSI adapter.

Supported Products / Add-on Adapters:
BusLogic 546C ISA SCSI Host Adapter
BusLogic 747C EISA SCSI Host Adapter
BusLogic 445C VL-Bus SCSI Host Adapter
BusLogic 946C PCI SCSI Host Adapter (rev C and D only)
BusLogic 948 PCI SCSI Host Adapter (not tested, reported to work)
BusLogic 958 PCI Wide SCSI Host Adapter (not tested, reported to work)

Supported Products / Systems (ie integrated into PC System):
Canon object.station 41

Special Features of Driver / Driver Notes:
The onboard floppy controller, available on some cards, is not supported.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

SCSI Driver Details

Supported Connectors: 50-pin Centronics (Standard SCSI), 50-pin Header (Internal SCSI)
Access Mode: DMA
Attributes*: SCSI-2
Cache Size Supported*: N/A

Known Problems

BusLogic firmware revs. before 4.25J may not work with this driver. In particular, firmware version 4.21 had a bug, which caused the Read Capacity data to be read up incorrectly.

BusLogic 946C rev A and B do not work with our driver.

Driver Name / Installer .pkg: CanonObjectstation41DisplayDriver
Driver Type: Display
Driver Scope: Specific Product
Supported Components: Brooktree Bt485 RAMDAC, C&T 64200 (Wingine)
PC Bus / Interface Supported by Driver*: Integrated

General Overview notes: This new graphics driver is designed to support the on-board Chips and Technologies Wingine graphics controller on the Canon object.station 41. The graphics subsystem of the object.station 41 was custom designed to operate with NEXTSTEP. The system uses a RAMDAC design modified to support NEXTSTEP's 4-4-4 internal 16bit color representation for improved graphics performance. This design includes 2MB VRAM and supports a variety of high resolution and high color (32bit) modes.

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):

Responder: When It Renames System at Startup

The Responder on my Macintosh LC makes me rename my computer every time I start it. I am running system software 6.0.7. Why does this happen?

This article has been archived and is no longer updated by Apple.
The first thing is to make sure you're using at least version 1.1.1 of Responder (actually, 2.0.x is the most recent version).

The next thing to check is the Get Info menu item in the Finder to see if the System file is locked. Responder writes the name of the client Macintosh to a resource in the System file. If the System file is locked, Responder is unable to make a permanent change to the System file.

Driver: Cirrus Logic GD5434
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/CLGD5434.pkg.compressed

Driver Name / Installer .pkg: CirrusLogicGD5434DisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: Cirrus Logic GD5430, Cirrus Logic GD5434, Cirrus Logic GD5436, Cirrus Logic GD5446
PC Bus / Interface Supported by Driver*: Integrated, PCI, VL-Bus

General Overview notes: This driver is intended to support on-board implementations of GD5434 as well as add-on adapters.

Supported Products / Add-on Adapters:
Diamond SpeedStar 64 (PCI)
Orchid Kelvin 64 (with GD5434)

Supported Products / Systems (ie integrated into PC System):
Elonex WS4100
Intel Premier (with integrated GD5434)
HP Vectra XM Series3 (not tested but reported to work)

Special Features of Driver / Driver Notes:
Because this chip has an integrated RAMDAC with only an 8 bit palette, Preferences's Brightness slider (and hardware gamma correction in general) doesn't work for any non-8 bit modes. Also 32-bit color modes (where supported) look dark. There is no fix for these problems.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB VRAM, 2MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1152x864 (2MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1280x1024 (2MB+), 800x600 (1MB+)

Known Problems

Cirrus Logic GD5430 and GD5436 are not supported but is reported to work with this driver.

The GD5436 & GD5446 do not support 32 bit color modes. Only 8 & 16 bit modes are available for adapters based on these chips.

Driver Version Notes

3.31 - Added support for PCI cards and 8 bit color
4.00 - Released on OPENSTEP 4.0 User CD-ROM
4.01 - Added support for GD5446 chipset

Driver Name / Installer .pkg: DECchip21040NetworkDriver
Driver Type: Networking
Driver Scope: Generic-Chipset
Supported Components: DEC DECchip21040, DEC DECchip21041
PC Bus / Interface Supported by Driver*: Integrated, PCI

General Overview notes: This networking driver supports most DECchip21040 & DECchip20141 based cards.

Supported Products / Add-on Adapters:
Cogent EM960 PCI
SMC PCI EtherPower (SMC 8432)
Digital EtherWORKS Turbo PCI (DE435)
Linksys EtherPCI LAN Card
DANPEX PCI Ethernet (EN-9400P3)
JCIS Condor (JC1260)
Kingston EtheRx PCI Ethernet (KNE40T & KNE40BT)

Supported Products / Systems (ie integrated into PC System):
DEC Celebris GL & GLST

Special Features of Driver / Driver Notes:
This driver replaces the Cogent EM960 PCI Ethernet Adapter driver.

Diamond Stealth OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Diamond Stealth
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.02, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/DiamondStealth.pkg.compressed

Driver Name / Installer .pkg: DiamondStealthDisplayDriver
Driver Type: Display
Driver Scope: Product Family
Supported Components: S3 732 (Trio32), S3 764 (Trio64), S3 764 (Trio64V+), S3 801, S3 805, S3 864 (Vision), S3 868 (Vision), S3 911
PC Bus / Interface Supported by Driver*: PCI, VL-Bus

General Overview notes: This graphics driver is designed to support the VL-Bus & PCI versions of the Stealth 64 and Stealth 3D Graphics adapters from Diamond Computer Corp. These cards are based on the or S3-968, S3-868, S3-Trio, or ViRGE graphics controller chipsets and support 2MB or 4 MB of RAM.

This driver replaces the older Diamond Stealth64 driver.

Supported Products / Add-on Adapters:
Diamond Stealth 64 DRAM PCI-Bus Display Adapter
Diamond Stealth 64 DRAM VL-Bus Display Adapter
Diamond Stealth 64 Video PCI-Bus Display Adapter
Diamond Stealth 64 Video VL-Bus Display Adapter
Diamond Stealth 64 VRAM PCI-Bus Display Adapter
Diamond Stealth SE PCI-Bus Display Adapter
Diamond Stealth SE VL-Bus Display Adapter
Diamond Stealth 64 DRAM T PCI-Bus Display Adapter
Diamond Stealth 64 DRAM T VL-Bus Display Adapter
Diamond Stealth 64 Video VRAM VL-Bus Display Adapter
Diamond Stealth 64 Video 3200 VL-Bus Display Adapter
Diamond Stealth 64 Video 2121XL DRAM PCI-Bus Display Adapter
Diamond Stealth 64 Video 3000 VRAM PCI-Bus Display Adapter
Diamond Stealth 3D 2000 PCI-Bus Display Adapter
Diamond Stealth 3D 3000 PCI-Bus Display Adapter

Special Features of Driver / Driver Notes:
This driver does not support gamma correction in 16 and 24 bit modes. This results in a somewhat dim screen when using 16 bits per pixel. Also, in these modes the brightness slider in preferences is inoperative.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM, 1MB VRAM, 2MB DRAM, 2MB VRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
1024x768 (4MB+), 1152x864 (4MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1152x864 (2MB+), 1280x1024 (4MB+), 1600x1200 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

· When used with the Diamond Stealth SE boards (both PCI and VL) configured for 800x600 8-bit Greyscale, some video artifacts and noise may be seen when viewing NeXTTIme movies or performing other graphics-intensive operations. One of the color modes is recommended if this occurs.

· Diamond has changed the PCI deviceID on their newer Stealth adapters. This will cause autodetection to fail, thus the NEXTSTEP driver will defualt to VGA display mode. Under NEXTSTEP 3.3, the workaround is to click Expert... while inspecting the driver in Configure.app, then modify the value of the Auto Detect setting to read 0x88d05333 0x88d15333 0x88f05333.

· Diamond Stealth 64 Series 2001 does not use an S3 controller, it uses the ARK Logic which is not supported.

Driver Version Notes

4.00 - Released on OPENSTEP 4.0 User CD-ROM
4.01 - Added support for ViRGE and ViRGE VX chipsets.

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

Personal LaserWriter NT: Cause of Partial Two-Sided Pages

When I try to print double-sided pages on a Personal LaserWriter NT using manual feed, very often the back side of the page doesn't print. Any ideas?

This article has been archived and is no longer updated by Apple.
This printing problem occurs if there is a delay feeding paper to the multi-purpose tray. The lower portion of the image will begin to disappear about 10 seconds after the Paper Out indicator lights, or about 4 seconds after the preceding page ejects. The amount of the image affected depends on the length of the delay. If too much time passes and the image disappears, the Personal LaserWriter NT will ignore that page entirely and continue with the rest of the print job.

Because double-sided printing requires feeding paper one sheet at a time, and because you must wait for the first sheet to complete before feeding the next, you have little time before the image begins to disappear.

The only workaround is to insert your pages more quickly. Before we figured out what was really happening, we noticed that the problem diminished the more we tried to reproduce it. We were getting better at feeding the paper, and so didn't cause a sufficient delay to see the problem.

DPT SCSI Family OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: DPT SCSI family
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: DPTSCSIDriver
Driver Type: SCSI
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver*: EISA, Integrated, ISA, PCI

General Overview notes: The DPT SCSI driver update is designed to support the 2000 and 3000 series of SCSI adapters from DPT. This driver does not support the DPT 2011 ISA Adapter. The DPT 32xx series SmartRAID SCSI adapters include RAID and Cache capability, and support from 1 to 3 SCSI channels. This driver replaces the NEXTSTEP 3.3 DPT 2000 Adapter driver.

Supported Products / Add-on Adapters:
Model# Bus Description
PM2021/90 ISA SCSI adapter
PM2021/95 ISA SCSI adapter
PM2022/90 EISA SCSI adapter
PM2022/95 EISA SCSI adapter
PM2024 PCI SCSI adapter
PM2041W * ISA Wide SCSI adapter
PM2042W * EISA Wide SCSI adapter
PM2044W * PCI Wide SCSI adapter
PM2122/90 EISA SCSI adapter
PM2122/95 EISA SCSI adapter
PM2124 PCI SCSI adapter
PM2124W PCI WIDE SCSI adapter
PM2142W * EISA Wide SCSI adapter

PM3021 ISA SCSI RAID controller (Not tested, should work)
PM3222 EISA SCSI RAID controller
PM3224 PCI SCSI RAID controller
PM3224W PCI WIDE SCSI RAID controller

DPT-TWR n/a 6-bay SCSI Tower
DPT-TWR/W n/a 6-bay WIDE SCSI Tower (Not tested, should work)

* These products have not yet been tested by NeXT's SQA Dept.

Supported Products / Systems (ie integrated into PC System):
NEC Express II P60 (On-Board)

Special Features of Driver / Driver Notes:
The onboard floppy controller, available on some cards, is not supported.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

EIDE OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: EIDE
Last Update: February 18, 1998

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated BETA version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/beta/EIDE.pkg.compressed

Driver Name / Installer .pkg: EIDE
Driver Type: System
Driver Scope: Generic-System
Supported Components: PC Tech RZ1000
PC Bus / Interface Supported by Driver*: Integrated, ISA, PCI
Supported Connectors: 40-pin Header (Internal IDE)
Access Mode: PIO
Adapter Memory:

General Overview notes: This drivers supports IDE disks and IDE ATAPI rev. 1.2 compliant CD-ROMs. It supports primary and secondary IDE controllers with up to 2 drives per controller.
This driver replaces the IDE driver distributed on the NEXTSTEP 3.3 CD.

Supported Products / Add-on Adapters:
The following ATAPI CD-ROM drives are supported:
Chinon CD-ROM CDS-525 (2X), firmware rev. W09
Matsushita CD-ROM CR-571 (2X), firmware rev. 1.0e -- Panasonic
Mitsumi CD-ROM 1B (4X), firmware rev. B02 -- model FX400
Sony CD-ROM CDU55E (2X), firmware rev. 1.0u
Sony CD-ROM CDU76E-S (4X), firmware rev. 1.0c
Toshiba CD-ROM XM-5302TA (4X), firmware rev. 0305
Philips CM207, firmware rev 1.10 (??) -- reported to work
SONY CD-ROM CDU76E-Q, firmware rev 1.0c (4X)
SONY CD-ROM CDU55D, firmware rev 1.0v (2X)
SONY CD-ROM CDU77E, firmware rev 1.0e (4X)
TORiSAN CD-ROM CDR-S1, firmware rev 1.70 (4X) -- SANYO
Chinon CD-ROM CDS-545, firmware rev ERc A1.0 (4X)
GoldStar CD-ROM GCD-R540, firmware rev 1.17 (4X)
GoldStar CD-ROM GCD-540C, firmware rev 1.01 (4X)
SANYO CRD-254P, firmware rev 1.02 (4X)
MATSHITA CD-ROM CR-574, firmware rev 1.06 (4X) -- Panasonic
Pioneer CD-ROM DR-UA124X, firmware rev 1.02 (4X) -- force detection
MITSUMI CD-ROM !B, firmware rev K02 (4X) -- DRM FX400B
TEAC CD-55E, firmware rev ?? (4X) -- Thinkpad 760CD
ATAPI CD-ROM SPEED-6X, firmware rev 6.2D (6X) -- ACER 665A
VERTOS 600ESD CD-ROM X6-IDE, firmware rev 1.20 (6X)
TEAC CD-56E, firmware rev 1.0D (6X)
MATSHITA UJDCD4700, firmware rev 1.11 (??)
TEAC CD-58E, firmware rev 1.1B (8X)
Toshiba CD-ROM XM-5602B, firmware rev 1426 (8X)
Sony CD-ROM CDU311, firmware rev 3.0i (8X)
EPSON CMD-2240 SPEED-6X, firmware rev R100 -- reported to work
Hitachi CDR-7730, firmware 1.1a (4X)
TEAC CD-524E, firmware 4.0D (24X)

Supported Products / Systems (ie integrated into PC System):
Other ATAPI 1.2 compliant CD-ROM drives should work with NEXTSTEP even if they are not in the supported list.

Special Features of Driver / Driver Notes:

NeXT's EIDE driver is not affected by the RZ1000 hardware bug.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Known Problems

These devices are not supported.
1. NEC CDR-260 (2X)
2. NEC CDR-273

To get the Pioneer DR-UA124X 1.02 CD-ROM to work you must force detection. You can do this by going in Expert mode and adding the key "Slave"="ATAPI" (or "Master" as the case may be) to the table.

Driver Version Notes

3.33 - This version adds support for several new ATAPI CD-ROM drives and fixes some bugs.
3.34 - Fixed a bug which could cause machines to hang under very heavy load. Released on OPENSTEP 4.0 User CD-ROM
4.02 - Added device overrides and modified the inspector. The new overrides are documented in the driver help.
4.03 - Improved ATAPI support. Added support for Intel PIIX PCI IDE controllers. Added Bus Master support. Revised the driver Inspector.

New Driver / Update Description:
Use the following installation instructions when installing from a CD-ROM drive connected to the secondary EIDE controller:

1. Select Primary/Secondary(Dual) EIDE and ATAPI Device Controllers as the hard disk driver.

2. After the install program has finished reading from the CD-ROM, the Configure panel will appear. Double-click the Other icon. If the Primary/Secondary(Dual) EIDE and ATAPI Device Controllers driver is listed, remove it from the list. It is no longer necessary since the installation from the CD-ROM is complete. Add the appropriate EIDE driver to match your EIDE hardware configuration. You will need to add it twice to get a second instance of the EIDE driver to support the secondary EIDE controller. You will need to set the IRQ to 15, and I/O port address range to 0x170-0x177 in the second instance of the driver, in order to avoid conflicts with the first instance. Add any other necessary drivers while in Configure, and then click on theSave button.

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

EISA Bus OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: EISABus
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/EISABus.pkg.compressed

Driver Name / Installer .pkg: EISABus
Driver Type: System
Driver Scope: Generic-System
Supported Components:

General Overview notes: This is a required driver that provides basic bus support for all system buses on Intel platforms. Without this driver, NEXTSTEP will not boot

Special Features of Driver / Driver Notes:
In order to better support various bus configurations, bus support was removed from the kernel and split into several bus drivers. All other bus drivers currently rely on the EISABus driver for basic services.

Driver Version Notes

3.31 - Allows Plug and Play to be turned off. This is required for Compaq's IBM Token Ring AutoSense 16/4 board to work in their PnP-Bios equipped machines ie. the Compaq Deskpro 5100 and Prolinea 575.
3.32 - Added "Force Cold Boot" switch to inspector panel. When this switch is turned on, the machine will be forced to go through a cold boot sequence every time it reboots
4.00 - Released on OPENSTEP 4.0 User CD-ROM
4.03 - Significant improvements to Plug and Play support. /usr/Devices/PnPDump is provided as a useful debugging tool.
4.05 - Updated PnP ID matching routine in order to work with ESS1868 based sound cards.

SMB File Transfer: Access over Ethernet

Will it ever be possible to access SMB servers over Ethernet?
This article has been archived and is no longer updated by Apple.
While the SMB protocols are not limited to Token Ring, they are usually used only with Token Ring. Since Apple's SMB File Transfer utility works so closely with the Texas Instruments Token Ring interface controller chip set on the TokenTalk NB card, it's difficult to port to an Ethernet environment without a major rewrite of the software.

A workaround is to use MacLAN Connect, a product that allows any PC or compatible to act as an AppleShare compatible server. All hard disks, LAN volumes or other storage devices are available to AppleShare-connected Macintosh workstations. MacLAN Connect supports LocalTalk, EtherTalk and TokenTalk.

General Overview notes: This device driver supports the built in LCD and external CRT display for IBM Thinkpad 755CX system. It supports 800x600 display in 16-bit color.

Supported Products / Systems (ie integrated into PC System):
IBM ThinkPad 755CX

Special Features of Driver / Driver Notes:
This driver can display in 1024x768 mode on an external CRT if the LCD is not active.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 1MB DRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:

16 Bit Color Modes*:
800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 800x600 (1MB+)

IBM ThinkPad 760CD OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: IBM ThinkPad 760CD Display
Last Update: November 7, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/beta/ThinkPad760CD.pkg.compressed

Driver Name / Installer .pkg: IBMThinkPad760CDDisplayDriver
Driver Type: Display
Driver Scope: Specific Product
Supported Components: Trident TGUI9320
PC Bus / Interface Supported by Driver*: Integrated

General Overview notes: This device driver supports the built in LCD and external CRT display for IBM Thinkpad 760CD system. It supports 800x600 color LCD as well as the external display connector.

Supported Products / Systems (ie integrated into PC System):
IBM ThinkPad 760CD

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)

IBM TokenRing OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: IBM Token Ring
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: IBMTokenRing
Driver Type: Networking
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver:** ISA

General Overview notes: This is the new version of the IBM Token Ring driver which adds support for the Auto sense adapters.

Supported Products / Add-on Adapters:
IBM 25F7367 (ISA, 16/4 Mbps, 8-bit, 64K)
IBM 25F9858 (ISA, 4Mbps, 8-bit, 16K)
IBM 67X0438 (ISA, 4Mbps, 8-bit, 16K)
IBM 60G3994A? (ISA, 16/4 Mbps, 16-bit, 64K)
IBM 92G7668 (Auto, ISA, 16/4 Mbps, 16-bit, 64K)
IBM 41H8450 (Auto, ISA, 16/4 Mbps, 16-bit, 64K)

Supported Products / Systems (ie integrated into PC System):
Token Ring option for Compaq DeskPro and Prolinea series

Special Features of Driver / Driver Notes:
3COM TokenLink III 3C619B (Auto, ISA, 16/4 Mbps, 64k) (untested) is reported to work using the "IBM Auto 16/4 Token Ring ISA Adapter" personality.

Networking Driver Details

Network Type*: Token Ring
Speed*: 16 Mb/s, 4 Mb/s
Access Mode*: Memory Mapped
Buffer Size*: 64KB
Supported Connectors*: STP, UTP

Driver Version Notes

3.33 Support Auto 16/4 and add Fast Path Transmit
3.34 Survive being disconnected from the MAU, both at boot time and during operation. Fix problem with being the first node on the network.
3.36 Fix problems on a busy token ring. Symptoms include netboot flakiness/receive congestion errors. Performance improvements were also made.
3.37 Fix problem with using an MTU too large for 4Mbit rings. The driver now limits the MTU to 4472 when it automatically switches to 4Mbit/s. The MTU is also limited by the ring speed selection made on the driver's Configure panel.
4.00 - Released on OPENSTEP 4.0 User CD-ROM

AppleWorks: Using Spreadsheet data with Business Graphics II

This article discusses how to convert AppleWorks date to work with the Business Graphics II application.
This article has been archived and is no longer updated by Apple.
To convert Appleworks Spreadsheet data to work with Business Graphics II (from Business and Professional Software), first use AppleWorks to print the Spreadsheet data to a ProDOS Data Interchange Format (DIF) file.

From AppleWorks you can then convert this ProDOS DIF file to a DOS 3.3 DIF file. Business Graphics II can read this DOS 3.3 DIF file and plot the file's data.

AppleShare File Server: Multilaunch Management Utilities

Are there any AppleShare utilities that limit the number of copies made of applications on the server?

This article has been archived and is no longer updated by Apple.
Here are two programs that restrict launch restrictions on AppleShare:

KeyServer

Developed and used at Dartmouth and available from Sassafras Software, is a launch control package which also provides rwall and motd capability.

LaunchBreak

Developed by the University of Michigan's Computer Aided Engineering Network, LaunchBreak 1.0.3 is available to not-for-profit educational institutions.

LaunchBreak's features:

* Monitors the usage and enforces an upper limit for copying applications on an AppleTalk network.

* Applications running under LaunchBreak can be rendered useless outside of a site's network, hindering software piracy.

* Applications can be located anywhere on the network.

* Doesn't interfere with legitimate copying of programs for backup. Applications can be freely copied, although the copied programs are still subject to control of LaunchBreak.

* The license server can run as a foreground application on an AppleShare server, or on another machine on the network.

* Remote administration of the license server

* Statistical record keeping on all server transactions.

System Requirements:

* System 6.0 or later

* AppleTalk Data Stream Protocol (ADSP).

This article has been archived and is no longer updated by Apple.
Driver: IDE
Last Update: December 18, 1997

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: IDE
Driver Type: System
Driver Scope: Generic-System
Supported Components:
PC Bus / Interface Supported by Driver*: Integrated, ISA
Supported Connectors: 40-pin Header (Internal IDE)
Access Mode: PIO
Adapter Memory: N/A

General Overview notes: This driver is obsolete and had been replaced by the EIDE driver.

Special Features of Driver / Driver Notes:
Always use the large disk option while installing NEXTSTEP.

Known Problems

Also supports PCI IDE adapters.

Intel 82365 and Compatible OPENSTEP Driver Overview

This article discusses a device driver for OPENSTEP versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Intel 82365 and compatible PCMCIA chipset
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: PCIC
Driver Type: System
Driver Scope: Generic-Chipset
Supported Components: Intel i82365
PC Bus / Interface Supported by Driver*: PCMCIA
Supported Connectors:
Access Mode:
Adapter Memory:

General Overview notes: This driver supports the Intel 82365 chip set, which is used to provide PCMCIA socket support.

Supported Products / Add-on Adapters:
SwapBox Classic MMCD-D - Not test by SQA, might work.

Supported Products / Systems (ie integrated into PC System):
NEC Versa E Series
NEC Versa V Series
NEC Versa 4000
Compaq LTE Elite
IBM Thinkpad 755CX
IBM Thinkpad 760CD
Adaptec CardPark

Special Features of Driver / Driver Notes:
This driver is necessary when using the Intel 82365 PCMCIA chipset with PCMCIA devices. See also NeXTanswer 1801_PCMCIABus

Known Problems

Hot insertion and removal of PCMCIA devices is not supported.

Driver Version Notes

3.31 - Fixes a bug which could result in inconsistent adaptor initialization.
3.32 - Adds support for PCIC compatible PCI-PCMCIA Bus Bridges
4.01 - Released on OPENSTEP 4.0 User CD-ROM

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

No updated versions of this driver are available

Driver Name / Installer .pkg: Intel824X0
Driver Type: System
Driver Scope: Generic-Chipset
Supported Components: Intel i824x0
PC Bus / Interface Supported by Driver*: Integrated

General Overview notes: This driver fixes a flaw the the Intel 824X0 PCI chipsets. It only needs to be installed on PCI systems based on the Intel 82420 & 82430 chipsets.

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Driver Version Notes

3.30 - Initial Version - disables all PCI write-posting
3.31 - Re-enable PCI write-posting, on those systems that can safely support them.
4.00 - Released on OPENSTEP 4.0 User CD-ROM

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

Driver Name / Installer .pkg: Intel82556NetworkDriver
Driver Type: Networking
Driver Scope: Product Family
Supported Components: Intel i82556
PC Bus / Interface Supported by Driver:** EISA, PCI

General Overview notes: This driver supports Intel EtherExpress PRO/100 adapters based on the Intel 82556 chipset.

Supported Products / Add-on Adapters:
Intel EtherExpress PRO/100 EISA LAN Adapter (EILA8265)
Intel EtherExpress PRO/100 PCI LAN Adapter (PILA8465)

Special Features of Driver / Driver Notes:
This driver does not support Model B of the Intel EtherExpress PRO/100 PCI Ethernet Adapter. Model B is supported by the Intel 82557 Network Driver

Networking Driver Details

Network Type*: 100 Base TX, EtherNet
Speed*: 10 Mb/s, 100 Mb/s
Access Mode*: Bus Master DMA
Buffer Size*: N/A
Supported Connectors*: UTP

Driver Name / Installer .pkg: Intel82557NetworkDriver
Driver Type: Networking
Driver Scope: Product Family
Supported Components: Intel i82557, Intel i82558
PC Bus / Interface Supported by Driver*: PCI

General Overview notes: This driver supports the Intel EtherExpress PRO/100+, PRO/100(model B), and the PRO/10+ PCI adapters. The PRO/100+ adapter used the 82558 ethernet controller, while the other two adapter families uses the 82557 controller.

Supported Products / Add-on Adapters:
Intel EtherExpress PRO/100+ PCI LAN Adapter (10Base-T, 100Base-TX)
Intel EtherExpress PRO/100 PCI LAN Adapter (PILA8465BX) (10Base-T, 100Base-TX)
Intel EtherExpress PRO/100 PCI LAN Adapter (PILA8475B) (10Base-T, 100Base-T4)
Intel EtherExpress PRO/10+ PCI LAN Adapter (PILA8500) (BNC, AUI, RJ-45)
Intel EtherExpress PRO/10+ PCI LAN Adapter (PILA8520) (RJ-45)

Networking Driver Details

Network Type*: 100 Base T4, 100 Base TX, EtherNet, Full Duplex
Speed*: 10 Mb/s, 100 Mb/s
Access Mode*: Bus Master DMA
Buffer Size*: N/A
Supported Connectors*: AUI, BNC, UTP

Driver Version Notes

3.30 - Initial beta version
3.32 - Improved performance; added workaround for intermittent receiver errata to prevent hang
4.00 - Released on OPENSTEP 4.0 User CD-ROM (based on 3.32)
4.03 - Added support for Pro/10+ PCI adapter
4.05 - Added support for 82558 based adapters

Driver Type: Networking
Driver Scope: Generic-Chipset
Supported Components: Intel i82595
PC Bus / Interface Supported by Driver*: ISA, PCMCIA

General Overview notes: This driver supports many Ethernet adapters which use the Intel82595 LAN Chipset.

Supported Products / Add-on Adapters:
Cogent EM595 TP (PCMCIA, UTP)
Cogent EM595 C (PCMCIA, UTP/BNC) - Not testeed, but should work
Cogent EM525 (ISA, BNC/AUI) - Not tested, but should work
Cogent EM525 TP (ISA, UTP) - Not tested, but should work
Cogent EM525 C (ISA, BNC/UTP/AUI)
Intel EtherExpress PRO/10 ISA (BNC/UTP/AUI)
Intel EtherExpress PRO/10 ISA Plug and Play (BNC/UTP/AUI)
Intel EtherExpress PRO/10+ ISA Plug and Play (BNC/UTP/AUI)

Networking Driver Details

Network Type*: EtherNet
Speed*: 10 Mb/s
Access Mode*: PIO
Buffer Size*: 64KB
Supported Connectors*: AUI, BNC, UTP

Known Problems

· This driver has not been tested with the Cogent 525 series, but should work.
· If you have stepping 3 of the EtherExpress Pro/10, the driver will complain with en0: 82595 unsupported stepping (3), but will continue to work

Driver Version Notes

3.30 Initial version
3.31 Added support for EE Pro/10 ISA
3.33 Added support for EE Pro/10+ ISA
4.00 Released on OPENSTEP 4.0 User CD-ROM
4.04 Added support for Plug and Play versions of the PRO/10 and PRO/10+. The Plug and Play versions of this driver require the latest EISABus driver version to be installed before configuring this driver.

MacX: Window Position Problem (4/93)

Article Change History

04/20/93 - UPDATED
* To include MacX 1.2 information.

I'm using FrameMaker on a Sun, displaying in MacX 1.0. Some rootless windows are displaying their title bars underneath the MacX menu bar. MacX sets the top left corner of the X display server to be at (0,0), rather than compensating for the fact that the Macintosh menu bar is 20 pixels or so tall. I can't move these windows because I can't access their title bars.

I can adjust the window prefs file on the host, but the problem happens because of MacX's rootless operation, regardless of the host process.

This article has been archived and is no longer updated by Apple.
If your title bars are hidden under the Macintosh menu bar, drag the window out of the Macintosh menu bar while holding down the OPTION key.

Yes, it is true that the MacX 1.0 to 1.1.7 Window Manager sets the upper-left corner of the screen at origin (0,0). The Macintosh menu bar (MacX application in this case) is accounted in the entire screen coordinates. Therefore, when specifying the y coordinate for a rootless window, the height of the title bar must be taken into consideration. Otherwise, the application's title bar will be hidden under the Macintosh menu bar.

The MacX Window Manager automatically positions a window:

* if its display coordinates are off screen
or * if the command to create it doesn't have a geometry option
or * if the geometry option's x,y coordinates are 0,0
MacX 1.2 will position the window just below the menu bar.

A/UX: How to Collect System Crash Information (8/94)

How can I get an operating system dump when A/UX either hangs or crashes?
Is there any documentation on interpreting such output?

This article has been archived and is no longer updated by Apple.
Currently A/UX provides no BSD UNIX styled "crash" system dump. However, A/UX does provide a basic kernel debugger (a module linked into the kernel).

To make a kernel that contains the "debugger" module, invoke the "newconfig debugger" command to build a new kernel. To boot a kernel that contains the "debugger" module, make sure that the "launch" from the A/UX Startup contains the -s option. The -s option causes "launch" to load the kernel symbol table into memory and allows the debugger to display addresses as symbolic names.

To use the debugger, connect an ASCII asynchronous terminal to the modem port (tty0). The debugger reads from and writes to the modem port at 9600 speed with 8-bit characters.

Two ways you can activate the debugger:

* by pressing the programmer's interrupt switch to produce a non-maskable level 7 interrupt.

* by calling the debugger's "sysdebug()" routine.

The above information was documented in greater detail in the Release notes for "A/UX Device Drivers Kit Version 2.0". This kit is no longer available.

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Number Nine Motion771
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: Number9Motion771DisplayDriver
Driver Type: Display
Driver Scope: Specific Product
Supported Components: IBM RGB524 RAMDAC, S3 968 (Vision)
PC Bus / Interface Supported by Driver*: PCI, VL-Bus

General Overview notes: This driver supports both 2MB & 4MB versions of the Number Nine MotionFX 771 display adapter. Both PCI & VL-Bus models are supported

Supported Products / Add-on Adapters:
Number Nine 9FX Motion 771 2MB PCI (NB9FX2-771-2P)
Number Nine 9FX Motion 771 4MB PCI (NB9FX2-771-4P)
Number Nine 9FX Motion 771 2MB VL-Bus (NB9FX2-771-2VL)
Number Nine 9FX Motion 771 4MB VL-Bus (NB9FX2-771-4VL)

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB VRAM, 4MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
1024x768 (4MB+), 1152x864 (4MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1152x864 (2MB+), 1280x1024 (4MB+), 1600x1200 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 1600x1200 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Driver Version Notes

3.30 - First version of the driver supports 2MB/4MB PCI/VL models using the S3/968 & IBM RGB524 RAMDAC.
4.00 - Released on OPENSTEP 4.0 User CD-ROM

A/UX 2.0.1: Function Keys and CommandShell

Does A/UX 2.0.1 support the function keys in the CommandShell?

This article has been archived and is no longer updated by Apple.

Yes, A/UX 2.0.1 supports the Apple Extended Keyboard function keys in both the CommandShell environment and console emulator mode. In addition, A/UX 2.0.1 supports VT100 application keypad mode in the CommandShell environment, but not, however, in console emulator mode.

The console(7) manual pages provide more information on this subject.

PCMCIA Bus OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: PCMCIABus
Last Update: October 28, 1996

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.02, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/beta/PCMCIABus.pkg.compressed

Driver Name / Installer .pkg: PCMCIABus
Driver Type: System
Driver Scope: Generic-System
Supported Components:

General Overview notes: This driver provides PCMCIA Bus Services to the NEXTSTEP Operating System, PCMCIA Device Drivers, and to Configure. NEXTSTEP requires this driver if the system contains a PCMCIA slot

Known Problems

This driver does not support hot swapping of PCMCIA devices. In particular, attempting to hot swap the Adaptec SlimSCSI PCMCIA adapter can hang your machine.

Driver Version Notes

3.30 - Released on NEXTSTEP 3.3 User CD-ROM
3.31 - Fixed several bugs. Added support for cards needing shared memory.
3.33 - Added Auto-Detect logic; improved boot messages.
3.34 - Added support for level irqs required by EtherLink III adapter
4.00 - Released on OPENSTEP 4.0 User CD-ROM
4.02 (&3.35) - Audio is now enabled on a per-card basis. Verion 4.02 (& v3.35) enables Audio for any PCMCIA device that includes "Enable Audio" = "Yes"; in its Instance.table. For example: To enable Modem audio, add this key to the Serial Port Instance.table that corresponds to the Modem.

PATHWORKS-DECnet: Wide-Area Network Issues

I have a VAX in two countries: Hong Kong and Korea. Both sites have AppleTalk networks connected using PATHWORKS. I would like to connect these networks using X.25 (using VAX PSI software).

According to Digital and PATHWORKS documentation, I can run full DECnet over VAX PSI and have completely integrated operation. If I run PATHWORKS (AppleTalk-to-DECnet gateway), will I still have this level of transparency?

The literature I have read states that I can do this. But will I have to keep the X.25 link on all the time? How expensive is this? Or is the PSI software intelligent enough to connect to the X.25 network only when actually needed?
This article has been archived and is no longer updated by Apple.
In theory, your setup should work. As long as you have a line and a circuit between the two DECnet nodes, creating the DECnet tunnel is just a matter of defining the "tunnel" port, giving it a name, taking care of routing costs, turning on the system, and (most important) specifying a partner (the DECnet node name of the other VAX).

In practice, you may encounter these problems:

* With AppleTalk 3.0 for VMS, we don't recommend any tunneling below 56KB. In many X.25 networks, the connection between the computer and X.25 pad may be slower than the connection between the pads.

* The X.25 link should be up all the time. There is no way for DECnet PSI software to be dynamically connected and "know" when AppleTalk packets should go through. Even if the software could do this, the tunnel port definitions on both ends can't be dynamic.

* If your X.25 network has any two-minute delays, AppleShare will have problems. The ASP session timer expires at two minutes, terminating the session and losing the server connection.

* Another problem has to do with NBP lookup. You might not see the file server when opening the Chooser and selecting the AppleShare icon. Some sites have to change a resource called GNRL to increase the Chooser interval timer and retry timer values.

You can find a complete discussion of this subject in the Tech Info library in AppleLink. For more information, search on "AppleTalk and Wide and Area".

S3 Generic OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: S3 Generic
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.03, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/S3Generic.pkg.compressed

Driver Name / Installer .pkg: S3GenericDisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components: S3 732 (Trio32), S3 764 (Trio64), S3 764 (Trio64V+), S3 801, S3 805, S3 864 (Vision), S3 868 (Vision), S3 911
PC Bus / Interface Supported by Driver*: Integrated, PCI, VL-Bus

General Overview notes: This driver will support a variety of video display devices based on S3 chipsets. It is primarily intended to support implementations based on the S3 Vision864, Vision868, ViRGE, though it should also support many adapters based on other S3 products such as the Vision964, Vision968, Trio32, Trio64, & ViRGE/VX chips.

This driver is a generic chipset driver and as such, is only intended to be used as a last resort. If a driver is available that specifically supports your display adapter, that driver should be used rather than this generic driver.

Apple does not guarantee that this driver will work with any specific adapters or implementations, but expects that it will support many.

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: .5MB DRAM, 1MB DRAM, 1MB VRAM, 2MB DRAM, 2MB VRAM, 4MB DRAM, 4MB VRAM, 8MB VRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
1024x768 (4MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1280x1024 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1280x1024 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

Driver Version Notes

3.32 - Added support for the Trio64V+ chipset
4.00 - Released on OPENSTEP 4.0 User CD-ROM

S3 ViRGE OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: S3 ViRGE Display Driver
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.01, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/S3ViRGE.pkg.compressed

Driver Name / Installer .pkg: S3ViRGEDisplayDriver
Driver Type: Display
Driver Scope: Generic-Chipset
Supported Components:
PC Bus / Interface Supported by Driver*: PCI

General Overview notes: This driver supports the Number Nine Reality 332 and Diamond Stealth 3D 2000 display adapters. Other S3 ViRGE implementations that adhere to S3's reference BIOS should be supported as well.

Supported Products / Add-on Adapters:
Number Nine 9FX Reality 332 PCI Display Adapter
(90-332010-000, 91-332010-000, 91-332013-000)
Diamond Stealth 3D 2000 PCI Display Adapter

Special Features of Driver / Driver Notes:
The 1152x864 modes listed below are supported only by the Number9 Reality 332 Display Adapter. These modes are not available on the Diamond Stealth 3D 2000, and are not supported on generic S3/ViRGE implementations.

This adapter is not recommended for applications requiring 32 bit color; 32 bit modes will appear dim because the hardware does not implement gamma correction.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 2MB EDO DRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes*:
640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes*:
1024x768 (2MB+), 1152x864 (2MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes*:
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 640X480 (1MB+), 800x600 (1MB+)

SCSI Tape OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: SCSITape
Last Update: December 18, 1997

Availability Information

No updated versions of this driver are available

Driver Name / Installer .pkg: SCSITape
Driver Type: System
Driver Scope: Generic
Supported Components:
PC Bus / Interface Supported by Driver*: SCSI
Supported Connectors:
Access Mode: Indirect Driver
Adapter Memory:

General Overview notes: This is a SCSI Tape peripheral driver. It supports most SCSI tape drives that use the generic SCSI command set for Tape Devices. A SCSI Host Adapter and associated NEXTSTEP driver are required in order to use this driver

Special Features of Driver / Driver Notes:
Sun DAT drives cause other tape drives with higher SCSI ID's to not be registered. This is a hardware problem. The workaround is to place non-Sun tape drives at a lower SCSI ID than the Sun DAT drive.

Driver Version Notes

3.31 - Corrects a problem restoring data from tapes. This problem was encountered when using /dev/rst# device nodes, where # is a number. This problem only effects tape reads, so tapes written using this driver should be correct.
4.00 - Released on OPENSTEP 4.0 User CD-ROM

MacX25: Using with Macintosh IIsi Issues

I installed MacX25 on a Macintosh IIsi and then tried to start the MacX25 Admin program. The MacX25 Admin program doesn't recognize my AppleSerial NB Card: I keep getting a "Status" "Out of service" message.

Is this a known problem?
This article has been archived and is no longer updated by Apple.
You are mostly likely using the first version of MacX25; the MacX25 server and MacX25 Admin software version 1.0 doesn't work on any computer that requires System Software 6.0.7 (such as the Macintosh IIsi). The problem involves the "Gestalt" function and is fixed in version 1.0.1 of MacX25.

Version 1.0.1 of MacX25 is compatible with both System 6.0.7 and System 7. To use the MacX25 server software under System 6.0.7, you'll need at least 2MB of RAM. Under System 7, you'll need at least 4MB of RAM.

LisaCalc 3.0: Problems Handling Large Documents

This article has been archived and is no longer updated by Apple.
LisaCalc has difficulty handling documents over 400 blocks long. If you try to build a file that large, an error may occur after you save and put away the document. If you attempt to redisplay it, you may see a dialog box saying "Unable to Redisplay the Document."

These problems have been fixed in Lisa Office System Release 3.1. The new LisaCalc size limit is approximately 700 blocks (350K). Larger documents still require much more time to calculate, update, print, and save.

Do I have to use the LaserWriter 6.0.1 driver if TrueType is installed?

This article has been archived and is no longer updated by Apple.
The TrueType software that comes with the StyleWriter or Personal LaserWriter LS printer requires the LaserWriter 6.1 driver or later. The driver is on the Macintosh Printing Tools disk that comes with the StyleWriter printer. Everyone on the network should upgrade together to the newest driver.

The LaserWriter 6.1 driver doesn't use the separate Laser Prep file required by previous versions of the LaserWriter driver. Instead the Laser Prep code is downloaded with every print job. Because of this, users of this driver will not have Laser Prep "wars" when new versions of LaserWriter drivers are installed.

There is a Laser Prep file on the above printing disk, but only for upgrading AppleShare Print Servers that makes them compatible with the new LaserWriter driver. Here is the path:

SoundBlaster 16 OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Sound Blaster 16
Last Update: December 22, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
An updated release version of this driver, version 4.01, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/released/SoundBlaster16.pkg.compressed
An updated BETA version of this driver, version 4.02, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/drivers/beta/SoundBlaster16.pkg.compressed

Driver Name / Installer .pkg: SoundBlaster16
Driver Type: Sound
Driver Scope: Product Family
Supported Components:
PC Bus / Interface Supported by Driver*: ISA

General Overview notes: This driver support most SoundBlaster 16 and 100% compatible sound cards.

Supported Products / Add-on Adapters:
Sound Blaster 16 Basic (ISA)
Sound Blaster 16 Value (ISA)
Sound Blaster 16 AWE (ISA)
Sound Blaster 16 SCSI-II (ISA)
Sound Blaster 16 Value PnP (ISA)
Sound Blaster AWE 32 (ISA)
Sound Blaster AWE 64 Value (ISA)
Sound Blaster AWE 64 Gold (ISA)

Special Features of Driver / Driver Notes:
Only simple playback and recording are supported. Wave table related hardware is unsupported.

The SCSI interface on the Sound Blaster 16 SCSI-II has been reported to work with our Adaptec 6x60 driver, though is not a supported configuration.

This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Sound Driver Details

Supported Connectors: 1/8" Microphone In, 1/8" Stereo Line-In, 1/8" Stereo Line-Out, 1/8" Stereo Speaker , CD-ROM Stereo Line-In
Access Mode: DMA
Adapter Memory:
Attributes: 16-bit Linear, 8-bit Linear

Known Problems

In order to configure resources (like IRQ, DMA, port addresses) correctly, make sure that the system BIOS knows about the resources used by this and other ISA adapters.

Use the PnP personality for SB16 PnP boards and enable support for Plug and Play in the EISABus driver.

Driver Version Notes

3.33: Added support for Plug and Play cards.
4.00: Released on OPENSTEP 4.0 User CD-ROM
4.01: Updated the PnP personality tables. Improved reliability of sound playback and recording.

DIGICARD: Connects Computers to DigiCard Networks (6/97)

Can a Macintosh LC attach to DigiCard network?

This article has been archived and is no longer updated by Apple.
DIGICARD can connect Apple Macintosh 512kE, Macintosh Plus, Macintosh SE, Macintosh LC, Macintosh Classic, and Macintosh IIsi computers to its networking system without any extra hardware. All that is required for each Macintosh is an external isolater box such as PhoneNet or DIGICARDs own brands AppNet, or for more permanent installations, a wallplate outlet called Cablepoint.

Apple IIe, Apple IIGS, and IBM PC compatibles require a network interface card to connect to the DIGICARD network. There are three types of interface cards: one for the Apple IIe or Apple IIgs, one for the Apple IIgs only, and one for IBM PC compatibles.

MacLagan & Wright are the developers of DIGICARD. They are based in Australia.

Macintosh: Multi-line Dial-in Access Software

I'm looking for a multi-line remote-access AppleTalk server or bulletin board system for the Macintosh.

Also, how do I go about setting up such a system?

This article has been archived and is no longer updated by Apple.

Multiple calls on a single phone number ("one-number access") are available from your local telephone company. This is the same service many businesses use for voice services.

Apple Remote Access MultiPort Server is a product from Apple that provides a flexible, scalable, and secure way to offer network access to large numbers of remote or mobile users. Used in conjunction with one or more Apple Remote Access Serial Cards, it allows a Macintosh computer or a Workgroup Server to support from 4 to 16 simultaneous dial-up connections.

On the client side users would have the Apple Remote Access Client for Macintosh software on their system to connect to a Apple Remote Access MultiPort server.

Another solution for allowing multiple dial up lines into an AppleShare network would be the use of network modems such as Shiva's NetModem. These modems are stand-alone AppleTalk devices that connect as a node. One NetModem would be required for each incoming line. Once connected, the computer dialing in would become a node on the network via the NetModem.

TeleFinder, by Spider Island Software, is a bulletin board program for the Macintosh that handles multiple callers. The program provides electronic mail (its own, not a gateway to other systems) and file transfers. It also sports a Macintosh interface: files and folders appear and behave much as they do in the Finder. And while Macintosh users have the benefit of a graphical interface, other computer users can have access using text commands.

TeleFinder handles as many phone lines as host Macintosh memory and processing power allow: a standard Macintosh II with 8 MB of RAM could handle six lines at 9600 baud or twenty or more phone lines at 2400 baud. Be aware that the Macintosh cannot efficiently manage multiple serial port activity. Ten or more callers on one Macintosh will definitely result in significant performance degradation.

Multiport serial cards are available from Creative Solutions and Applied Engineering.

Xircom Performance Series OPENSTEP Driver Overview

This article discusses a device driver for the OPENSTEP Mach operating system, versions 4.0 through 4.2.
This article has been archived and is no longer updated by Apple.
Driver: Xircom Performance Series
Last Update: December 18, 1997

Availability Information

A version of this driver is on the OPENSTEP CD-ROM
No updated versions of this driver are available

Driver Name / Installer .pkg: XircomIIpsNetworkDriver
Driver Type: Networking
Driver Scope: Product Family
Supported Components: Xircom Scipper/2
PC Bus / Interface Supported by Driver*: PCMCIA

General Overview notes: This driver supports the Xircom Performance Series PCMCIA Ethernet Adapters.

Supported Products / Add-on Adapters:
Xircom PS-CE2-10BT (PCMCIA, UTP)
Xircom PS-CE2-10BC (PCMCIA, UTP/BNC)

Networking Driver Details

Network Type:** EtherNet
Speed*: 10 Mb/s
Access Mode:** PIO
Buffer Size*:
Supported Connectors:** BNC, UTP

Known Problems

NeXT is investigating performance problems experienced with Version 2.10 of the Xircom Performance Series adapters. Once the problem is identified and resolved, a fixed version of the driver will be made available.

Driver Version Notes

3.31 - Initial beta release
3.32 - Released QA'd version
3.33 - Updated to be compatible with Version 3.34 of the PCMCIABus driver.
4.00 - Released on OPENSTEP 4.0 User CD-ROM

* - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed.

OPENSTEP 4.0 Supplemental Release Notes

This file supplements not only the on-line release notes included on both the OPENSTEP 4.0 and OPENSTEP Developer 4.0 CD's (both Windows and Mach), but also any printed release notes packaged with those releases.

Installation

Systems with the ªWindows 95 Shellº

OPENSTEP 4.0 for Windows won't install correctly on systems running the combination of Windows NT 3.51 and the beta version of the ªWindows 95 shell.º However, OPENSTEP 4.0 for Windows installs correctly on Windows NT 3.51 systems without the shell, as well as on systems running the beta versions of Windows NT 4.0. Upgrading an NEC Express II/P60 ST

If you're planning to upgrade an NEC Express II / P60 ST from NEXTSTEP 3.3 to OPENSTEP 4.0 for Mach, please read the following:

The DPT2000 SCSI driver is now obsolete and has been replaced by the more generic DPTSCSI driver along with a ªdriver personalityº<the DPT On-Board SCSI driver<that's been created specifically for the NEC Express II / P60 ST. Unfortunately, machines running NEXTSTEP 3.3 with the DPT 2021 ISA SCSI personality installed and configured don't upgrade properly to the new DPT On-Board SCSI driver personality, preventing the machine from booting after the upgrade.

You can prevent this by using either of the following procedures:

· *Before upgrading to OPENSTEP 4.0*, download the DPTSCSI driver from NeXTanswers (**http://www.next.com/NeXTanswers/HTMLFiles/1889.htmld/1889.html**). Install the driver, then launch Configure.app. In Configure, select the SCSI icon, remove the curent driver, and add the DPT On-Board SCSI driver. Reboot and upgrade normally.

or,

· After upgrading, don't click on the Restart button in Upgrader. Instead, launch Configure.app, select the SCSI icon, remove the current driver, and add the DPT On-Board SCSI driver personality.

If you've already upgraded and cannot boot into OPENSTEP 4.0 for Mach, boot from the OPENSTEP installation boot diskette. Simply insert the disk into the disk drive, power on the machine, then type the following at the ªBoot:º prompt:

```
fd()mach_kernel rootdev=sd0
```

Follow the on-screen directions. Once OPENSTEP has booted, log in as **root** and launch Configure.app. In Configure, select the SCSI icon, remove the current SCSI driver, and add

the DPT On-Board SCSI driver personality.

Drivers

Pathlight SSA Driver

The Pathlight SSA driver is considered a beta-quality driver since it hasn't been officially tested by NeXT's Quality Assurance department. We recommend that you download and install the released version of this driver once it becomes available.

Intel82557 Network Driver

The Intel82557NetworkDriver is considered a beta-quality driver. There is one known bug in the driver which prevents the adapter from connecting with the network. This has been fixed in the latest 4.0 Beta driver, which can be obtained from NeXTanswers (**http://www.next.com/NeXTanswers/NABrowse?/NEXTSTEP/Intel_Configuration_Information/Drivers/4.0_Drivers/Beta**). We recommend that you download and install the released version of this driver once it becomes available.

Interface Builder

Nib File Compatibility

Any nib file generated by Interface Builder under OPENSTEP 4.0 (Windows or Mach) that contains a text object won't be OpenStep compliant.

LaserWriter 6.0: How To Get Black & White Update Patch

How can I obtain the LaserWriter 6.0 driver with the patch that has black and white selected as the default?

This article has been archived and is no longer updated by Apple.
The LaserWriter 6.z.1 driver is on AppleLink in the Tech Info Library. Use the search criterion of "LaserWriter 6.z.1".

Also, the LaserWriter 6.1 driver defaults to black and white or Color/Gray scale, depending on what was used last. The LaserWriter 6.1 driver is on the Macintosh Printing Tools disk that comes with the Personal LaserWriter LS and the StyleWriter.

Macintosh: Where To Find DRAM for Old-Style Video Boards

I want to upgrade my old 4-bit video card to 8-bit. Apple's memory upgrade kit for the old video card is now off the price list. I assume that these are just standard 64K DRAMs. Can you recommend a third-party source?

This article has been archived and is no longer updated by Apple.
The memory chips used to expand the old Macintosh II Video Card from 4-bit to 8-bit are not standard 64K DRAMs. VRAMs made by NEC were used on the board (part numbers: D41264C-12). The "-12" in the part number indicates that the chips have a 120ns rating.

Companies that sell these chips include:

* The Chip Merchant
* SHECOM COMPUTERS
* Peripheral Outlet

To locate a vendor's address and phone numbers, use the vendor name as a search string.

OPENSTEP 4.1 Installation for Windows NT 4.0

Unless otherwise stated, this information applies to NT 4.0 Gold and OPENSTEP/NT 4.1 only. The information presented here may or may not apply to versions of NT before 4.0 gold, or OPENSTEP/NT 4.0. You must performall of the following procedures as Administrator.
This article has been archived and is no longer updated by Apple.

Q: What does the OPENSTEP/NT Distribution install on my system?

A:

- All files are installed under the directory defined by the NEXT_ROOT environment variable.

- 2 services: machd and nmserver (in OPENSTEP 4.0, these are simply programs in the common StartUp group)

- 2 programs in the common startup group:pbs and WindowServer

- environment variables either added or changed: NEXT_ROOT, Lib, Path

- Registry entries (do a search for NeXT)

Q: How do I Manually uninstall OPENSTEP/NT 4.0?

A:

1. Quit any running OPENSTEP Applications

2. Kill the four daemons: machd, nmserver, pbs, WindowServer. They do not show up on the task list, so you will have to use pview or the Task Manager in NT 4.0 in order to kill them. Alternatively, remove the programs from the StartUp folder,and reboot your machine.

3. Remove the four daemons from the common StartUp folder.

4. Delete the entire NEXT_ROOT directory.

5. Remove or change the NeXT related environment variables: NEXT_ROOT, Lib, Path.

6. (Optional) Remove any registry references to NeXT software using the Registry Editor.

Q: How do I install OPENSTEP/NT 4.1 on NT 3.51?

A: Very carefully.

Changes were made in NT 4.0 gold that broke the installation process for OPENSTEP during the 4.1 beta process. We have fixed OPENSTEP/NT 4.1 so that it installs cleanly on NT 4.0 Gold, but this consequently broke the installation for NT 3.51. You can still successfully instally on NT 3.51 by following these steps:

1. Install as usual, but when asked if you want the installer to place programs in your startup folder, choose NO. The installation will complete successfully.

2. Place pbs and WindowServer in the common StartUp group.

pbs is in %NEXT_ROOT%\\NextLibrary\\Frameworks\\AppKit.Framework\\resources\\pbs.exe
WindowServer is in %NEXT_ROOT%\\NextLibrary\\System\\WindowServer.exe

3. (Optional) Create a NeXT program group and create the file extension associations within File Manager.

4. Reboot the machine.

Q: How do I Manually uninstall OPENSTEP/NT 4.1?

A:

1. Quit any running OPENSTEP Applications

2. Kill the four daemons: machd, nmserver, pbs, WindowServer. You must bring up the Services control panel to stop machd and nmserver. You can use pview or the NT 4.0 Task Manager to kill pbs and WindowServer. Alternatively, remove the programs from the StartUp folder,and reboot your machine.

3. Remove machd and nmserver as services. From the command prompt, type (replacing %NEXT_ROOT% with the actual NeXT root directory):
%NEXT_ROOT%\\NextLibrary\\System\\machd -remove
%NEXT_ROOT%\\NextLibrary\\System\\nmserver -remove

4. Remove pbs and WindowServer from the common StartUp folder.

5. Delete the entire NEXT_ROOT directory.

6. Remove or change the NeXT related environment variables: NEXT_ROOT, Lib, Path.

7. (Optional) Remove any registry references to NeXT software using the Registry Editor.

Q: I've installed OPENSTEP correctly, but it still won't run. What's wrong?

A: OPENSTEP must believe your NT system has network capability in order to run.

The nmserver service must have networking enabled in order to run. You can either put your NT machine on a network, or configure RAS to work around this. You need not connect to a service provider with RAS; just have it configured. If you have an ethernet card in your machine, removing it will make RAS configuration easier.

OPENSTEP 4.1 Development for Windows NT 4.0

This document contains information on developing OPENSTEP 4.1 applications on Windows NT 4.0 Gold. The information presented here may or may not apply to versions of NT before 4.0 gold, or to other versions of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Q: Why does my application say "Class not loaded" at run time even though I clearly have the framework linked into my project?

A:

Even though it looks like your app build properly, the linker will not actually link in a dll unless you make direct reference to a symbol in the dll. Here is an example of how to directly reference symbols, taken from the template EOF application:

```
#ifdef WIN32
#import <EOControl/EOControl.h>
#import <EOAccess/EOAccess.h>
#import <EOInterface/EOInterface.h>

void _referenceAllEOFrameworks()
{
static id a,b,c;
a = [EODisplayGroup new]; // EOInterface
b = [EOEntity new]; // EOAccess
c = [EOEditingContext new]; // EOControl
}
#endif
```

You never need to call this code. Simplying having it in your project is sufficient.

Q: Why do I get error LNK 1120: unresolved externals even though I clearly have the framework linked into my project?

A:

There is a bug in the OPENSTEP/NT 4.1 makefiles that will not export symbols from subprojects within a framework. You can add the following to the Makefile.postamble in your main project as a workaround.

```
ifeq "WINDOWS" "$(OS)"
$(WINDOWS_DEF_FILE): $(OFILES) $(OTHER_OFILES)
$(SILENT) if [ ! -r "./$(WINDOWS_DEF_FILE)" ] ; then \\
$(ECHO) -n "Generating $(notdir $@)...." ; \\
(cd $(OFILE_DIR); $(DUMP_SYMBOLS) $(OFILES) $(OTHER_OFILES) `$(CAT) $(NAME).ofileList` | $(EGREP)
"(SECT).*(External).*(\\|)" | $(EGREP) -v "(__GLOBAL_$I)|(_OBJC_)" | $(SED) "s/ _/ /" > $(TMPFILE)) ; \\
$(ECHO) "LIBRARY $(NAME).dll" > $(GENERATED_DEF_FILE) ; \\
$(ECHO) "EXPORTS" >> $(GENERATED_DEF_FILE) ; \\
$(CAT) $(TMPFILE) | $(EGREP) "(SECT2)|(.objc_c)" | $(AWK) '{printf "\\t%s CONSTANT\\n", $$NF}' >>
$(GENERATED_DEF_FILE) ; \\
$(CAT) $(TMPFILE) | $(EGREP) -v "(SECT2)|(.objc_c)" | $(AWK) '{printf "\\t%s\\n", $NF}' >>
$(GENERATED_DEF_FILE) ; \\
$(RM) $(TMPFILE) ; \\
$(ECHO) "done"; \\
fi
endif
```

Also, globals and functions are not automatically exported from a framework. See below for the workaround.

Q: Why will a project build sometimes fail for seemingly no reason in the link stages?

A: Because you may have the executable running or open in gdb

You may sometimes get errors that look like the following when trying to build your project under NT:
D:/NeXT//NextDeveloper/Libraries/libNSWinMain.a
LINK : fatal error LNK1104: cannot open file "C:/Projects/ImageCrop/ImageCrop.debug/ImageCrop.exe"
gcc: Internal compiler error: program ld got fatal signal 127
make[1]: *** [C:/Projects/ImageCrop/ImageCrop.debug/ImageCrop.exe] Error 1
make: *** [debug] Error 2

This is likely caused by the fact that the application is either still running, or you still have a debug session running. On NT, it is impossible to delete or overwrite a file while some process is using it.

Q: Why do I get a segmentation fault when trying to use a bundle?

A:

There is a problem with code in a bundle trying to access global variables in the main application. Typically, when the bundle code tries to access the global variable, you will get a segmentation fault. The solution is to put these global symbols into a framework and link both the application and the bundle against the framework. You must also implement additional declarations (see below) to export symbols other than class and category names from your frameworks.

Q: How do I export symbols other than class names from my framework?

A:

The makefiles that ship with OPENSTEP/NT will build a framework properly with class and category names exported, but functions and public variables are not exported. You must take special measures to export them explicitly.

You can create a header file like the one below and include it in your framework, to be both included by the framework and applications that link against the framework.

```
#ifdef WIN32

#ifndef _BUILDING_MY_FRAMEWORK
#define _MY_FRAMEWORK_GOOP __declspec(dllimport)
#else
#define _MY_FRAMEWORK_GOOP __declspec(dllexport)
#endif _BUILDING_MY_FRAMEWORK
```

```
#ifdef __cplusplus
#define MY_FRAMEWORK_EXTERN _MY_FRAMEWORK_GOOP extern "C"
#define MY_FRAMEWORK_EXTERN extern "C"
#else
#define MY_FRAMEWORK_EXTERN _MO_WINDOWS_DLL_GOOP extern
#define MY_FRAMEWORK_PRIVATE_EXTERN extern
#endif __cplusplus

#endif WIN32
```

You could then create public header files in your framework that use the macros in this header file to export symbols. For instance:

```
#ifdef WIN32
#import "MyFrameworkGoop.h"

// This function is public
MY_FRAMEWORK_EXTERN somePublicFunction();
// This function is private to the framework
MY_FRAMEWORK_PRIVATE_EXTERN int somePrivateVariable;

#endif WIN32
```

Q: Why can't I debug bundles and frameworks?

A: gdb cannot read symbols from relocated bundles and frameworks under NT.

Both bundles and frameworks are dynamically loaded code, and may be relocated in memory if there is a conflict with previous dynamic loaded code. Typically, you will be able to debug the first bundle and framework loaded, but not subsequent ones. You can avoid relocation of dynamically loaded code by specifying a base address to the linker so that your code will be loaded in a non-conflicting range of memory.

Add the following lines to your Makefile.preamble.

For frameworks, use:
WINDOWS_PB_LDFLAGS = -image_base 0x00000000 (fill in an address)

For Bundles, use:
WINDOWS_PB_LDFLAGS = -Xlinker "/BASE:0x00000000" (fill in an address)

A good address to use would be the ones that you see the code being relocated to as things load in gdb.

NeXTSTEP and OPENSTEP Time Zone Patch

This README document describes how to install the TimeZone Patch Update and describes the fixes contained in the update. This update is to be installed only on computers running NEXTSTEP 3.3, NEXTSTEP 3.3risc, OPENSTEP 4.0 for Mach, OPENSTEP 4.0 for NT, OPENSTEP 4.1 for Mach, and OPENSTEP 4.1 for NT. This problem has been corrected in OPENSTEP 4.2.

The 7th European Union Directive on Summer Time specifies that starting in 1996, Daylight Saving Time in the European Union will terminate on the last Sunday in October of each year. NeXT current software (including NEXTSTEP, OPENSTEP for Mach, and OPENSTEP for NT) thinks that DST in the European Union terminates on the last Sunday in September of each year.

To guarantee the integrity of the fixes included in this patch, you should only install this software when received from an authorized NeXT representative or a NeXT server. Your existing NeXT Software License Agreement governs the use of this software update. This patch updates only binary data files containing timezone information. It does not update any executables or scripts or documentation.

The OPENSTEP Current Patch List, **Document 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read this document if you're not sure which patches you need on your system.

Caution: You should make sure to back up your files before installing this patch update. On Mach, you should back up your /private/etc/zoneinfo and /usr/template/client/etc/zoneinfo directories. On NT, you should back up your $NEXT_ROOT/NextLibrary/Foundation.framework/Resources/TimeZoneInfo directory.

This article has been archived and is no longer updated by Apple.
Installing the TIMEZONE Patch Update on Mach

After downloading the Mach patch file from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/patches/4.1_TimeZone_Patch/TimeZonePatch_Mach.compressed

decompress it and follow these instructions to install the TimeZone Patch Update

1. Log in as root. (If you're not sure how to log in as root, see your system administrator.)

2. Make sure your computer is running NEXTSTEP 3.3, NEXTSTEP 3.3risc, OPENSTEP 4.0 for Mach, or OPENSTEP 4.1 for Mach. (You can find the version number with the Workspace Manager application's Info Panel command.)

Warning: Installing the TimeZone Patch Update on a computer that isn't running one of the above releases may result in unexpected problems.

3. Double-click the TimeZoneUpdate.pkg file.

4. Click the Install button in the Installer package window. An Install Package panel opens.

5. Click Install in the Install Package panel, and if prompted for confirmation, click OK to proceed.

The Installer window displays information about the progress of the installation.

6. Log out and restart the computer. You are now finished installing the patch.

Note: You may wish to confirm via your Date & Time system preferences in the /NextApps/Preferences.app that your computer's time zone is set correctly.

Installing the TIMEZONE Patch Update on NT

After downloading the NT patch file from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/patches/4.1_TimeZone_Patch/TimeZonePatch_NT.tar

follow these instructions to install the TimeZone Patch Update

1. Log in as Administrator onto your OPENSTEP for NT system. (If you're not sure how to log in as Administrator, see your system administrator.)

2. Make sure your computer is running OPENSTEP 4.0 for NT, or OPENSTEP 4.1 for NT. (You can find the version number with the Workspace Manager application's Info Panel command.)

Warning: Installing the TimeZone Patch Update on a computer that isn't running one of the above releases may result in unexpected problems.

3. Obtain a Bourne Shell prompt. This is located in the OPENSTEP Program Group.

4. Type cd·$NEXT_ROOT/NextLibrary/Frameworks/Foundation.framework/Resources/TimeZoneInfo. The $NEXT_ROOT environment variable refers to the top-level directory where the OPENSTEP software is installed.

5. Type $NEXT_ROOT/NextDeveloper/Executables/Utilities/gnutar.exe xvf tzupdate.tar. If you do not have a gnutar.exe file, you can download one from:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/openstep/patches/4.1_TimeZone_Patch/gnutar.exe

6. If the file $NEXT_ROOT/NextLibrary/Frameworks/Foundation.framework/Resources/TimeZoneInfo/localtime exists, then delete it.

7. Copy the appropriate timezone file to the file name localtime. For example, to make the default time zone GB-Eire, type cp -p GB-Eire localtime. Alternatively, you can add the environment variable TZFILE to your environment using the System control panel. The value of the variable should be the path to the appropriate time zone configuration file relative to $NEXT_ROOT/NextLibrary/Frameworks/Foundation.framework/Resources/TimeZoneInfo. For example, to set your time zone to be GB-Eire, the value of the TZFile environment variable would be "GB-Eire".

8. Log out and restart the computer. You are now finished installing the patch.

TIMEZONE PATCH UPDATE Release Notes

The remainder of this file describes the bug fixes that comprise the TimeZone Patch Update.

Problems Fixed in This Patch Update

TA45855_NeXTSTEP_and_OPENSTEP_Time_Zone_Patch.pdf

The following problems have been fixed in this update:

TimeZone Data

Reference: 67469, 63998

Problem: European timezone information is incorrect for end of summer time (Daylight Saving Time).

Fix: For the affected European timezones, the timezone data now correctly ends summer time on the last Sunday in October, in accordance with the European Union's 7th Directive on Summer Time.

NeXTSTEP 3.3 Driver: DEC21142 Network

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/DECChip21142Net.pkg.compressed

Driver Name / Installer .pkg: DEC21142Network
Driver Type: Networking
Driver Scope: Specific Product
Supported Components: DEC 21142, DEC 21143
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This driver supports the onboard ethernet LAN adapter in the DEC Celebris 61xx. The adapter is based on the DEC21142 chipset.

Supported Products / Add-on Adapters:

Supported Products / Systems (ie integrated into PC System):
DEC Celebris 61xx On-Board LAN Adapter

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Networking Driver Details

Network Type:** EtherNet
Speed*: 10 Mb/s
Access Mode:** Bus Master DMA
Buffer Size*:
Supported Connectors:** AUI, BNC, UTP

Known Problems

In the system BIOS setup screen (F2 at boot), be sure to set "Plug and Play OS" to "off". If left on, the driver will fail to retrieve the correct ethernet address (it will most likely be ff:ff:ff:ff:ff:ff).

Driver Version Notes

3.31 Initial version supporting 10 Mbit/s only.
3.32 Adds support for DECchip21143 in 10 Mbit/s mode.

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

OPENSTEP 4.1 Release Notes: Application Kit

This document contains release notes for OPENSTEP version 4.1.
This article has been archived and is no longer updated by Apple.

New Features in 4.1

ComboBox

The NSComboBox class has been added to the Application Kit. It offers similar functionality to the Combo Box control defined in the Microsoft° Windows, user interface.

Splash Screen

OPENSTEP for Windows now provides support for a "splash" screen in applications<basically a panel that comes up with a static image as the application is being launched. To use this feature, simply provide an 8-bit uncompressed bmp image named **Splash.bmp** as a resource in your application. You can make it localizable if you wish. (Thus the image will be either in *appname*.app/Resources or *appname*.app/Resources/*language*.lproj.) At launch time, the image will be loaded and displayed before any other initialization in the application, and will be removed from the screen before the first window is displayed.

For other changes in 4.1 please refer to the "Changes since 4.0" section below.

New Features in 4.0

OpenStep

OpenStep brings numerous API changes to the AppKit relative to Release 3.3. These changes and the tools provided for applications to convert to OpenStep are described in **/NextLibrary/Documentation/NextDev/Conversion/ConversionGuide**, available on OPENSTEP for Mach.

New Text System

4.0 includes a new text system composed of several different classes: NSTextView (front-end UI), NSTextStorage and NSAttributedString (back-end text storage), NSLayoutManager (management of text layout process and info), and NSTextContainer (description of text flow areas). These classes provide an open, powerful interface and allow text editing in multiple languages, using the Unicode standard. Please refer to the documentation for detailed info. An overview can be found in **/NextLibrary/Documentation/NextDev/TasksAndConcepts/ProgrammingTopics/TextOverview.rtfd** (Mach) or in the **/NextLibrary/Documentation/NextDev/TasksAndConcepts/Topics.hlp** (Windows). There is also a separate release note which describes some of the defaults that can be used to customize the new text system and how to remap or add to the standard supported keybindings. In addition to these notes, the source code to several text-specific examples, including the full source to TextEdit, can be found in the **/NextDeveloper/Examples/AppKit** directory.

TableView

TableView has been completely rewritten and moved into the AppKit. All four classes making up the new TableView are public and fully subclassable.

Keyboard UI

Keyboard access is now provided to most of the controls in the AppKit. For more information, see the separate Keyboard UI Release Notes.

Formatting and Validation

Cells may now be assigned arbitrary object values, which are converted into presentation strings by associated formatter objects. This allows the developer to directly set an NSDate, for instance, as the value of a cell. The cell's associated date formatter will present a localized string representation of the date to the user. The formatter objects, along with control delegates, can also perform validation on user-entered data, thereby restricting entries to valid ranges or quantities, for instance only allowing dates between January 1, 1995 and June 30, 1995.

Rich Text in Cells

NSCell and subclasses can now display and edit rich text. The rich text is specified via instances of NSAttributedString. The new formatting/validation API also includes support for attributed strings.

RulerView

NSRulerView is designed as a general-purpose ruler that can be associated with any scroll view and used by any view that's in the scroll view. It supports both horizontal and vertical rulers, allows arbitrary markers along the rule, and can accept an accessory view.

System Colors

New API has been added to access system-defined colors, such as the color of buttons, controls, text and text selection colors. On Windows, where the user can change the system colors at any point, these colors will change at runtime to match the user's selection.

Help System

The AppKit's Help API has changed significantly. NSHelpPanel has been obsoleted in favor of a new class, NSHelpManager, which provides a more platform-independent approach to presenting help.

Known Problems in This Release

NSComboBox

Reference: 71826

Problem: NSComboBox should support keyboard interface

Description: NSComboBox does not support keyboard accelerators to open, dismiss, or navigate its popup list.

Workaround: None.

Reference: 60438

Problem: NSComboBox uses a private cell class.

Description: For the OPENSTEP 4.1 release, the cell class for NSComboBox is private.

Workaround: None.

NSTableView

TableView does not yet have printing support.

Reference: 51731

Problem: TableView does not fully support keyboard ui

Description: Only simple tabbing between editable cells is implemted in TableView. Arrow keys do not affect selection.

Workaround: Override keyDown: in a subclass or in the owning window and change the selection accordingly.

Reference: 63967

Problem: Header and row height do not change relative to font size

Description: When the developer changes the font size of the header view cells or data cells in a TableView, the heights of the header view and rows do not change appropriately.

Workaround: Manually change the height of the header view and row height.

NSCell

Reference: 52511

Problem: **setUpFieldEditorAttributes:** called only when editing

Description: **setUpFieldEditorAttributes:** is not called when non-editable text is displayed in cells. This makes it difficult to change colors in custom subclasses of NSCell.

Workaround: To display colored text in cells, text fields or attributed string values may be used.

NSImage

Reference: 60413

Problem: JPEG TIFFs don't work on Windows.

Description: Because the imageserver process is not yet available under Windows, JPEG TIFFs cannot be loaded in.

Workaround: None. The images can be compressed using another compression scheme using tiffutil on OpenStep for Mach.

New Text System

Reference: 58479

Problem: Rotated text views don't so selection very well

Description: The selection drawing (at least) in a rotated NSTextView needs work. The selection is generally drawn too large and leaves pixels around.

Workaround: None. Avoid editable rotated NSTextViews for now.

Reference: 50123

Problem: Some features are currently unimplemented

Description: The following features are currently unimplemented: Full justification, tabs other than left, certain paragraph style attributes, scaled images.

Workaround: None.

Reference: 54951

Problem: Screen fragments in containers with holes

Description: If you attempt to create an NSTextContainer with holes such that one physical line can have multiple line fragments, there are still problems with erasing old drawing below the hole when text is deleted.

Workaround: None.

Reference: 49744

Problem: Images are not scaled in scaled text

Description: Using the standard NSTextAttachment class, the images appear at 100%.

Workaround: This problem can be fixed by using a custom attachment cell.

Reference: 68768

Problem: Sometimes two lines will appear on top of each other

Description: The backing store is fine, but the text is laid out with two lines right on top of each other. This is fairly rare but somewhat disconcerting.

Workaround: Typing a character in the overlapped lines and then deleting it will fix the layout.

NSWindow

Reference: 71671

Problem: "Flash active caption bar" visual warning option might cause apps to hang

Description: If you have enabled SoundSentry (under Accessibility Options in the Control Panel), and turned on "Flash active caption bar" visual warning option, there is a good chance apps will hang when they call NSBeep(). This function is called by the Application Kit in a few cases<when you perform an unrecognized command key, for instance.

Workaround: None. Use one of the other visual warning options.

Reference: 72040

Problem: Resizing a modal panel causes it stop processing mouse down events

Description: If you resize a modal panel it will stop responding to mouse down events until it is dismissed and brought back on the screen again.

Workaround: Because keyboard events still work, you can dismiss the panel by navigating to the appropriate button via keyboard UI.

Reference: 71648

Problem: Closing a modal window or panel does not always end the modal session

Description: Closing a modal window or panel by clicking on the close box will not always end the modal session, leaving the application in a state where mouse clicks and key strokes are ignored. On Windows, modal panels often have a close box. This acts the same as a cancel button and, by default, clicking the close box while running modal will stop the modal session with the NSCancelButton return code. However, if the Window's delegate decides to control when the window should close by implementing windowShouldClose:, then it is also up to the delegate to stop the modal session in windowWillClose:. On Mach, modal windows and panels rarely have a close box; if they do they must stop modal in windowWillClose:.

Workaround: On Windows, a window delegate implementing windowShouldClose should stop the modal session in windowWillClose:. On Mach, any modal window or panel with a close box should stop the modal session in windowWillClose:

Reference: 64988

Problem: NSBackingStoreNonretained don't work under Windows

Description: Under Windows, nonretained windows aren't implemented.

Workaround: Use retained or buffered windows instead.

Reference: 69973

Problem: Miniaturizing and then restoring a window under Windows causes first responder to be lost

Description: When a window is miniaturized it loses track of its current first responder. When it is restored again, the first responder is not restored.

Workaround: You can use makeFirstResponder to set a first responder yourself or just make the user click something.

Reference: 69327

Problem: Clicking in the contents a window which is key won't bring it to the front

Description: Under Windows, if a non-key panel is in front of the key window, clicking in the content view of the key window will not bring it to the front.

Workaround: Clicking the title bar will bring it to the front.

Drag/Drop

Reference: 60829

Problem: On Windows, **ignoreModifierKeysWhileDragging** is never invoked on drag source

Workaround: None.

Reference: 67620

Problem: On Windows **draggedImage** always returns nil.

Description: During a dragging session, the DraggingInfo will always return nil when queried for its

draggedImage.

Workaround: None.

Reference: 63466

Problem: On Windows, the drag source's image offset is ignored

Description: Currently the dragged image will appear to the lower right of the cursor's hot spot.

Workaround: None.

NSFont

Reference: 61824

Problem: Microsoft's *WingDings* font is not supported well under OPENSTEP for Windows

Description: There isn't currently a Unicode mapping for any of the glyphs in it, even into the User Zone, so it works as any other "unknown" font (i.e., characters 0-255 are mapped directly to glyphs 0-255).

Workaround: None.

Keyboard UI

Reference: 51182

Problem: AccessoryViews are not added to keyView loop

Description: When a panel supporting accessory views, such as the SavePanel, is brought on screen, the accessory views are not automatically added to the keyView loop.

Workaround: Add the accessory view to the keyView loop by hand using setNextKeyView: before brining the panel on screen.

NSOpenPanel

Reference: 63490

Problem: On Windows, one can open file packages but not directories without extensions.

Description: The OpenPanel on Windows does not provide a way to select and open plain directories. Clicking on directories without extensions will expand the directory rather than opening it. Directories with extensions are correctly dealt with as file packages.

Workaround: Either require selectable directories to have extensions or provide a well defined file inside the directory for the user to select.

Accessory Views

On Windows, the PageLayout panel does not yet support application supplied accessory views. Also on Windows, accessory views in the Open, Save and Print panels work only on NT 4.0, not NT 3.51.

Changes since 4.0

The following list all the API changes and some of the bug fixes that were done in the Application Kit

between 4.0 and 4.1.

Note that in your application if you use any API which was added between 4.0 and 4.1, your application might not run under 4.0. (If you are not deploying under 4.0, then this is not an issue.) You can catch some of the potential problems by defining **STRICT_40** at compile time. This #define is used in the Application and Foundation Kits to mark new API.

Similarly, if you rely on a bug fix done in 4.1, your application may not function correctly under 4.0. Make sure you test on your intended deployment platform.

NSApplication

IBOutlet and **IBAction** are now defined in the kit and automatically imported if you import **AppKit.h**. You can remove your own custom definitions of these (if you had any).

The **hide:** method has been changed to do nothing on Windows.

The default value of the **NSUseRunningCopy** command line option has been changed to YES. This means that anytime you cause a second copy of the application to be launched, it will connect you to the already running copy. You should also If you wish to run multiple copies of an application, you should use "-NSUseRunningCopy NO". You might need this if you need to debug a new instance of the application while it's already running.

Another change is that all command line options which are not defaults options (meaning a pair of arguments where the first one starts with a "-") are now treated as file names to be opened, as if they were prefixed with -NSOpen.

As a result of these two changes, you can now associate documents with OPENSTEP apps on Windows simply by providing the location of the app. The default command line provided by the Explorer will be enough to open documents and also connect to a running copy of the application, if there is one.

On Windows, **[NSApplication init]** (called by **sharedApplication**) changes the current directory to the root of the drive from which the application is launched. This is done in order to avoid problems associated with the application starting off in random places (such as the directory of a file wrapper, when launched by double-clicking on a file in a file wrapper). One consequence of this is that any directory changes which take place in the **main()** function, before **sharedApplication**, will fail to stick.

NSWindow

In OPENSTEP for Windows, document edited state is now indicated in the title bar by prefixing the title with an asterisk. OPENSTEP for Mach still uses a broken "X".

Tracking rects are now implemented on Windows.

The following are not actually changes since 4.1, but are a couple things to be aware of concerning NSWindows in OPENSTEP for Windows.

· Under Windows, the frameRect and contentRect are currently the same size. The frameRect of an NSWindow under OPENSTEP for WIndows NT does NOT include the title bar, menu bar, resize border, etc...

· Under Windows, the contentView while a window is miniaturized is a NSImageView, not the original contentView. The contentView is restored when the window is deminiaturized. This is necessary because under some versions of Windows NT, the same actual window is used when the window is full size or miniaturized. It is just moved and resized when miniaturing or restoring. Since most content views are not prepared to size themselves that small, the content view is removed from the window while it miniaturizes and is restored when the window is restored.

NSTableView

A new notification, **NSTableViewSelectionDidChangeNotification**, and a corresponding delegate method, **tableViewSelectionIsChanging:**, have been added to NSTableView. The existing **NSTableViewSelectionDidChangeNotification** is only sent after the user has moused up when changing a selection. The new notification is sent while the selection is changing.

NSSavePanel

The save panel will now put up an alert letting you confirm before you replace an existing file.

NSInputServer

The following methods were added to NSInputServer. They are sent by current input manager when the application changes state so that the server can update its concept of who's current. The actually "active" sender is the last one to have sent a **senderDidBecomeActive:** message. These methods may not arrive in the expected order.

```
- (void)senderDidBecomeActive:(id)sender;
- (void)senderDidResignActive:(id)sender;
```

This method is sent by input manager when the conversation within a particular sender changes:

```
- (void)activeConversationWillChange:(id)sender oldConversation:(long)conv newConversation:(long)new;
```

NSTextView

To allow entering a character without an appropriate keyboard, you can now use the Alt key in conjunction with the digit keys from the keypad. While holding down the Alt key, type the index of the desired character in the encoding of the current font (in most cases this will be the NEXTSTEP encoding). The appropriate character will be inserted into the text when the Alt key is released.

NSWorkspace

The **openFile:withApplication:** will now correctly open the file with the specified application. In 4.0 this method always returned NO when an application name was supplied.

OPENSTEP for Window now contains an "open" command. Like on Mach, "open filename" will open the specified file in its registered application. You can also use the "-e" flag to open the file in TextEdit or the "-a" flag to launch an application.

NSAttributedString

If supplied a plain text file, the **initWithPath:documentAttributes:** method will now go ahead and still create an attributed string from the plain text contents. Note that if the file looks like an RTF file (has the appropriate magic header), but fails to open, the method will still return nil.

NSColor

Unarchived NSColors and NSColors created with **colorWithCalibratedRed:green:blue:alpha:** and **colorWithCalibratedWhite:alpha:** will be replaced by the cached and uniqued colors returned by methods such as [NSColor whiteColor] if they are exactly the same. In some cases this will greatly reduce the number of colors created at runtime and speed up certain operations. However, in the unlikely event that this causes problems in your application, or prevents your 4.0 application from running correctly under 4.1, you can set the **NSCachedColorConversion** default to NO.

System colors (such as those returned by [NSColor controlColor]) have been improved to generate colors which match those used by Windows. Under 8-bit color this should result in a visible

improvement in certain color schemes.

Changes before 4.0

There are tops scripts to assist PR1 to PR2 and PR2 to 4.0 migration. Many of the API changes that have happened between prereleases can be automatically applied to your code with these commands:

```
tops -semiverbose -scriptfile /NextDeveloper/OpenStepConversion/ConversionScripts/PR1toPR2.tops *.[mchCM] *.psw *.pswm

tops -semiverbose -scriptfile /NextDeveloper/OpenStepConversion/ConversionScripts/PR2to40.tops *.[mchCM] *.psw *.pswm
```

Formatting and Validation

NSFormatter and NSDateFormatter have moved into the Foundation Kit. FoundationKit now also includes a number formatter. Imports of <AppKit/NSFormatter.h> or <AppKit/NSDateFormatter.h> will need to be changed to import the corresponding file from Foundation; imports of <AppKit/AppKit.h> don't need to be changed. The tops script mentioned above takes care of this. Also, a new NSNumberFormatter has been added.

The control delegate message **control:validateObject:** has been changed to **control:isValidObject:**.

NSApplication

NSApplication defines a new delegate method similar to **-application:openFile:** called

```
-(void)application:(NSApplication *)app printFile:(NSString *)path
```

Upon launching, an application scans its command line arguments for -NSOpen and, now, -NSPrint arguments. These arguments are followed by the path to a file to open or print respectively. NSApplication sends the above messages to its delegate if it responds in this way for the files specified on the command line. These messages are also invoked in response to Speaker/Listener interaction, but this aspect is perhaps less interesting to developers.

This new message (and the new command-line argument -NSPrint) is supported on both Mach and Windows.

Under Windows NT, when you install OPENSTEP, Explorer associations are automatically created for each file extension that the OPENSTEP applications claim. The file-type's icon is associated with its extension and Open and Print commands are registered as well. These commands work through the new command-line options, and can be accessed through Explorer's right-mouse context menu. So, for example, right clicking an RTF file in Explorer will give you a menu that includes both Open and Print as well as some other stuff. Choosing Open or Print will cause TextEdit to open or print the file. Open is registered as the default command for these file extensions, so double-clicking an RTF file will open it in TextEdit.

A new notification, **NSApplicationWillTerminateNotification,** has been added to OpenStep. It is sent before the Application's **terminate** method after **applicationShouldTerminate** is queried.

A Windows-specific method has been added to allow access to the Windows application handle. This will only be of interest to developers calling the Win32 API directly. (Arguments that varioius types of Windows handles are declared as void currently to avoid polluting the namespace with the vast amount of un-prefixed names in the Windows system headers.)

```
- (void * /*HINSTANCE*/)applicationHandle;
```

A Windows-specific method has been added to allow developers to look up an NSWindow object given a Windows HWND handle. This will only be of interest to developers calling the Win32 API directly.

```
- (NSWindow *)windowWithWindowHandle:(void * /*HWND*/)hWnd;
```

A Windows-specific method has been added for developers who choose to implement their own WinMain() function If you do so, call the method below before doing any other AppKit calls. The arguments are those passed to WinMain() from the system.

```
+ (void)setApplicationHandle:(void * /*HINSTANCE*/)hInstance
previousHandle:(void * /*HINSTANCE*/)PrevInstance
commandLine:(NSString *)cmdLine
show:(int)cmdShow;
```

NSTableView

The table view has a new mode where it resizes all the columns, not just the last one, to fill the scroll view. In this mode, if the table view fits exactly into its scroll view, and is then grown, it will grow all of its resizable columns to keep itself the size of the scroll view. Here are the new methods to enable this:

```
- (void)setAutoresizesAllColumnsToFit:(BOOL)flag;
- (BOOL)autoresizesAllColumnsToFit;
```

While tracking a cell or performing the table view's action, one may discover what cell was clicked on to cause the action to perform with these additional methods:

```
- (int)clickedColumn;
- (int)clickedRow;
```

NSAttributedString

Parts of NSAttributedString and NSMutableAttributedString have moved into the Foundation Kit. Just using Foundation, without the Application Kit, you can create and manipulate attributed strings; however you do not have access to the standard attribute types such as color, font, and paragraph style. The rest of the attributed string functionality is provided by categories in Application Kit.

The following names have changed in NSAttributedString:

```
NSAttributedStringEditedAttributes -> NSTextStorageEditedAttributes
NSAttributedStringEditedCharacters -> NSTextStorageEditedCharacters
```

The following methods to read RTF:

```
+ (NSAttributedString *)attributedStringFromRTF:(NSData *)rtfData;
+ (NSAttributedString *)attributedStringFromRTFD:(NSData *)rtfData;
+ (NSAttributedString *)attributedStringFromRTFDFile:(NSString *)rtfdPath;
```

have been replaced by:

```
- (id)initWithRTF:(NSData *)data documentAttributes:(NSDictionary **)dict;
- (id)initWithRTFD:(NSData *)data documentAttributes:(NSDictionary **)dict;
- (id)initWithPath:(NSString *)path documentAttributes:(NSDictionary **)dict;
- (id)initWithRTFDFileWrapper:(NSFileWrapper *)wrapper documentAttributes:(NSDictionary **)dict;
```

The optional dict argument is for returning document-wide attributes, which currently include "PaperSize", "LeftMargin", "RightMargin", "TopMargin", and "BottomMargin". Pass NULL for dict if you don't care about these.

The following methods to write RTF:

```
- (NSData *)RTFFromRange:(NSRange)range;
- (NSData *)RTFDFromRange:(NSRange)range;
- (BOOL)writeRTFDToFile:(NSString *)path atomically:(BOOL)flag;
```

have been replaced by:

```
- (NSData *)RTFFromRange:(NSRange)range documentAttributes:(NSDictionary *)dict;
- (NSData *)RTFDFromRange:(NSRange)range documentAttributes:(NSDictionary *)dict;
```

```
- (NSFileWrapper *)RTFDFileWrapperFromRange:(NSRange)range documentAttributes:(NSDictionary *)dict;
```

Pass nil for dict if you don't want to specify any of the document attributes.

To write RTFD to file you will need to send **writeToFile:atomically:updateFilenames:** to the NSFileWrapper you get back from **RTFDFileWrapperFromRange:documentAttributes:**. The updateFilenames: flag should usually be YES (unless you are doing a "Save To").

The following method names are changed in NSMutableAttributedString:

Before:

```
- (void)fixAttributesAfterEditingRange:(NSRange)range;
- (void)fixFontAttributeAfterEditingRange:(NSRange)range;
- (void)fixParagraphStyleAfterEditingRange:(NSRange)range;
- (void)fixAttachmentAfterEditingRange:(NSRange)range;
```

After:

```
- (void)fixAttributesInRange:(NSRange)range;
- (void)fixFontAttributeInRange:(NSRange)range;
- (void)fixParagraphStyleAttributeInRange:(NSRange)range;
- (void)fixAttachmentAttributeInRange:(NSRange)range;
```

The value of **NSAttachmentCharacter** has been changed from 0xF6FF to 0xFFFC to match the one proposed in the Unicode standard. Code which uses this value will need to be recompiled; places where this value is archived explicitly might need to check for the old value. (RTF files did archive this value, so no need for changes there.) If the old value ever appears in an attributed string at runtime, the new value will be used, and a warning will be generated (single warning per app session).

The method **updateAttachmentsFromPath:** has been added to NSMutableAttributedString to allow updating the file name information in all the attachments in the attributed string.

NSImage

NSImage now understands the bmp, ico, and cur image formats. ico and cur files with multiple images will be loaded as images with multiple representations. Typically these representations will have different sizes (unlike multiple-representation tiffs, which have different depths); by default, NSImage will choose the largest image when compositing.

Windows-specific methods have been added to NSImage and NSBitmapImageRep which allow creation of these objects from a Windows icon handle or bitmap handle. These will only be of interest to developers calling the Win32 API directly.

```
- (id)initWithIconHandle:(void * /* HICON */)icon;
- (id)initWithBitmapHandle:(void * /* HBITMAP */)bitmap;
```

setFlipped: and **flipped** have been brought back into the API.

Compositing Operation name changes

Some of the constants declared by DPSClient for various compositing operations have had their names corrected:

Old Name	New Name
NSCompositeDataOver	NSCompositeDestinationOver
NSCompositeDataInreplace	NSCompositeDestinationIn
NSCompositeDataOut	NSCompositeDestinationOut
NSCompositeDataAtop	NSCompositeDestinationAtop

NSCursor

In order to make NSCursor immutable, the following methods:

```
- (id)initWithImage:(NSImage *)newImage;
- (void)setImage:(NSImage *)newImage;
- (void)setHotSpot:(NSPoint)spot;
```

have been replaced by:

```
- (id)initWithImage:(NSImage *)newImage hotSpot:(NSPoint)aPoint;
- (id)initWithImage:(NSImage *)newImage
foregroundColorHint:(NSColor *)fg
backgroundColorHint:(NSColor *)bg
hotSpot:(NSPoint)hotSpot;
```

The color hints in the latter method are ignored in OPENSTEP for Windows and for Mach.

The **initWithImage:** and **setImage:** methods are somewhat generic and hard to detect, so the tops script might fail to catch all your uses.

Another change in NSCursor since PR2 is the support for custom cursor selections on Windows. OPENSTEP applications will use the correct arrow and I-beam cursors where applicable. If you ask for the image of one of these standard cursors on OPENSTEP for Windows, you will get back the correct image used by the system. You should note that the size of this image may be different than the traditional 16x16 used on Mach. For animated cursors you will simply get back the first frame.

NSText

The following method names are changed in the NSText API:

Before:

```
- (NSString *)text;
- (void)setText:(NSString *)string;
- (void)setText:(NSString *)string range:(NSRange)range;
- (void)replaceRange:(NSRange)range withRTF:(NSData *)rtfData;
- (void)replaceRange:(NSRange)range withRTFD:(NSData *)rtfdData;
- (void)setColor:(NSColor *)color ofRange:(NSRange)range;
- (void)setFont:(NSFont *)font ofRange:(NSRange)range;
```

After:

```
- (NSString *)string;
- (void)setString:(NSString *)string;
- (void)replaceCharactersInRange:(NSRange)range withString:(NSString *)aString;
- (void)replaceCharactersInRange:(NSRange)range withRTF:(NSData *)rtfData;
- (void)replaceCharactersInRange:(NSRange)range withRTFD:(NSData *)rtfdData;
- (void)setTextColor:(NSColor *)color range:(NSRange)range;
- (void)setFont:(NSFont *)font range:(NSRange)range;
```

NSTextView

The following methods are added to NSTextView:

```
- (void)pasteAsPlainText:(id)sender;
- (void)pasteAsRichText:(id)sender;

- (NSPoint)textContainerOrigin;
- (void)invalidateTextContainerOrigin;

- (NSRange)rangeForUserTextChange;
- (NSRange)rangeForUserCharacterAttributeChange;
- (NSRange)rangeForUserParagraphAttributeChange;

- (BOOL)smartInsertDeleteEnabled;
- (void)setSmartInsertDeleteEnabled:(BOOL)flag;
- (NSRange)smartDeleteRangeForProposedRange:(NSRange)proposedCharRange;
- (void)smartInsertForString:(NSString *)pasteString replacingRange:(NSRange)charRangeToReplace
beforeString:(NSString **)beforeString afterString:(NSString **)afterString;
```

The following method names are changed in the NSTextView API to allow richer specification of

selected text attributes:

Before:

```
- (void)setSelectionColor:(NSColor *)color;
- (NSColor *)selectionColor;
```

After:

```
- (void)setSelectedTextAttributes:(NSDictionary *)attributeDictionary;
- (NSDictionary *)selectedTextAttributes;
```

Underlining is now supported in the new text system; **NSSingleUnderlineStyle** has been added as a possible value for the **NSUnderlineStyleAttributeName** attribute.

The delegate method **textView:clickedOnCell:inRect:** has been added to indicate single-clicks on text attachments.

The method **attachmentForDraggedFilename:** has been removed from the API.

NSTextStorage

NSTextStorage now sends out notification messages after edits:

```
NSTextStorageWillProcessEditingNotification
NSTextStorageDidProcessEditingNotification
```

It also has a delegate who gets the following messages:

```
- (void)textStorageWillProcessEditing:(NSNotification *)notification;
- (void)textStorageDidProcessEditing:(NSNotification *)notification;
```

These methods are called during post-edit processing (basically after **endEditing** has been called, or, if endEditing was not in effect, after each edit that causes **edited:range:changeInLength:**). The first notification is sent before attributes are fixed, the second is sent after the attributes are fixed, but before the layout managers are notified. During the execution of **textStorageWillProcessEditing:** the delegate can change the attributed string all it wants; during **textStorageDidProcessEditing:** it should refrain from changing the character contents. The changes done by the delegate will not cause further notifications to be sent. However, during the execution of these methods and notifications the delegate and the observers can obtain information about what's changed via the following methods:

```
- (unsigned)editedMask;
- (NSRange)editedRange;
- (int)changeInLength;
```

NSTextStorage now also has a clear funnel point for all post-edit processing:

```
- (void)processEditing;
```

This method sends the above notification methods, calls **fixAttributesInRange:**, and informs the layout managers of the changes.

The following methods, now much less useful, have been removed from the API:

```
- (void)verifyEdited:(unsigned)mask range:(NSRange)range changeInLength:(int)delta;
- (void)notifyEdited:(unsigned)mask range:(NSRange)range changeInLength:(int)delta
invalidatedRange:(NSRange)invRange;
```

Subclassers, note: NSTextStorage is now a semi-abstract class. It implements change management (**beginEditing**/**endEditing**), verification of attributes, and layout management notification. The one aspect it does not implement is the actual attributed string storage--this is left up to the subclassers, which need to override the two NSMutableAttributedString primitives **replaceCharactersInRange:withString:** and **setAttributes:range:**. These primitives should perform the change then call **edited:range:changeInLength:** to get everything else to happen.

Here is a sample NSTextStorage subclasser:

```
@implementation SimpleTextStorage

/* Provide your own init methods, whatever you wish... Here we provide one (initWithAttributedString:) and override the DI from super (init). */

- (id)initWithAttributedString:(NSAttributedString *)attrStr {
if (self = [super init]) {
contents = attrStr ? [attrStr mutableCopyWithZone:[self zone]] :
[[NSMutableAttributedString allocWithZone:[self zone]] init];
}
return self;
}

- init {
return [self initWithAttributedString:nil];
}

- (void)dealloc {
[contents release];
[super dealloc];
}

/* The next set of methods are the primitives for attributed and mutable attributed string... */

- (NSString *)string {
return [contents string];
}

- (NSDictionary *)attributesAtIndex:(unsigned)location effectiveRange:(NSRange *)range {
return [contents attributesAtIndex:location effectiveRange:range];
}

/* In the mutable primitives (and any non-primitives which are overridden and which don't go through the primitives), we need to call edited:range:changeInLength: to allow the text storage change management to do its job. */

- (void)replaceCharactersInRange:(NSRange)range withString:(NSString *)str {
[contents replaceCharactersInRange:range withString:str];
[self edited:NSAttributedStringEditedCharacters
range:range
changeInLength:(int)[str length] - (int)range.length];
}

- (void)setAttributes:(NSDictionary *)attrs range:(NSRange)range {
[contents setAttributes:attrs range:range];
[self edited:NSAttributedStringEditedAttributes range:range changeInLength:0];
}

@end
```

NSFileWrapper

A new public class has been added to the AppKit. NSFileWrapper provides support for the concept of a document wrapper (like a .rtfd, .nib, or many other NEXTSTEP file types). The new text system uses this class to handle RTFD documents, but it is designed to be generally useful. It handles reading and writing file packages in the file system as well as serializing them for use with the Pasteboard. See the General Reference for details.

NSTextAttachment

The following changes in NSTextAttachment take advantage of NSFileWrapper:

Before:

```
- (id)initWithContentsOfFile:(NSString *)path;
- (BOOL)writeToFile:(NSString *)path atomically:(BOOL)flag;
```

After:

```
- (id)initWithFileWrapper:(NSFileWrapper *)fileWrapper; /* Designated initializer */
- (void)setFileWrapper:(NSFileWrapper *)fileWrapper;
- (NSFileWrapper *)fileWrapper;
```

The **name** and **setName:** methods have also been removed from the API.

NSParagraphStyle

Subclassers, note: **NSParagraphStyle** and **NSMutableParagraphStyle** used to be abstract; they are now concrete.

setParagraphStyle: has been added to NSMutableParagraphStyle to allow setting all the values with one call.

NSRulerView/NSRulerMarker

The delegate method **rulerView:willSetClientView:** has been added to NSRulerView to give the existing client a chance to clean up.

The following method names are changed in NSRulerMarker:

Before:

```
- (void)setLocation:(float)location;
- (float)location;
- (id)initWithRulerView:(NSRulerView *)ruler location:(float)location image:(NSImage *)image imageOrigin:(NSPoint)imageOrigin;
```

After:

```
- (void)setMarkerLocation:(float)location;
- (float)markerLocation;
- (id)initWithRulerView:(NSRulerView *)ruler location:(float)location image:(NSImage *)image imageOrigin:(NSPoint)imageOrigin;
```

NSWorkspace

The following NSWorkspace methods will raise under OPENSTEP for Windows to indicate that they are not implemented (and the return value, being wrong, shouldn't be relied upon):

```
- (BOOL)fileSystemChanged;
- (BOOL)userDefaultsChanged;
- (NSArray *)mountedRemovableMedia;
- (NSArray *)mountNewRemovableMedia;
```

The following methods are no-ops:

```
- (void)checkForRemovableMedia;
- (void)findApplications;
- (void)hideOtherApplications;
- (void)noteUserDefaultsChanged;
- (void)noteFileSystemChanged;
- (BOOL)getFileSystemInfoForPath:isRemovable:isWritable:isUnmountable:description:type:;
- (int)extendPowerOffBy;
- (void)slideImage:(NSImage *)image from:(NSPoint)fromPoint to:(NSPoint)toPoint;
```

In addition, note that the **NSWorkspaceRecycleOperation** will currently remove the files in OPENSTEP for Windows.

NSBrowser

The width of columns are now dealt with as floats rather than ints to be consistent with the rest of the AppKit:

Before:

```
- (void)setMinColumnWidth:(int)columnWidth;
```

```
- (int)minColumnWidth;
```

After:

```
- (void)setMinColumnWidth:(float)columnWidth;
- (float)minColumnWidth;
```

A couple other api items changed names:

Before:

```
- (void)drawTitle:(NSString *)title inRect:(NSRect)aRect ofColumn:(int)column;
- (BOOL)browser:(NSBrowser *)sender selectCell:(NSString *)title inColumn:(int)column;
```

After:

```
- (void)drawTitleOfColumn:(int)column inRect:(NSRect)aRect;
- (BOOL)browser:(NSBrowser *)sender selectCellWithString:(NSString *)title inColumn:(int)column;
```

Selection may now be done by index as well as path. Previously the developer was forced to resort to NSMatrix apis when trying to select a row in a browser column by index. Now she may use:

```
- (void)selectRow:(int)row inColumn:(int)column;
- (int)selectedRowInColumn:(int)column;
```

And the following delegate method was added in parallel to allow the delegate to perform the selection:

```
- (BOOL)browser:(NSBrowser *)sender selectRow:(int)row inColumn:(int)column;
```

Alerts

Two pairs of new functions have been added to support the alert styles found in the Windows UI. **NSRunInformationalAlertPanel()** and **NSRunCriticalAlertPanel()** take the same paramenters as **NSRunAlertPanel()**, but on Windows they present an alert with the "informational" or "critcal" icons, respectively. On Windows **NSRunAlertPanel()** presents an alert with the "warning" icon. On Mach calling any of the three functions produces the same UI. Also note that on Windows alerts have no title, so the title argument to these functions is not displayed in the UI. In addition, **NSGetInformationalAlertPanel()** and **NSGetCriticalAlertPanel()** have been added, which have the same relationship to the existing **NSGetAlertPanel()**.

The function **NSRunLocalizedAlertPanel()** is removed from the API; use **NSRunAlertPanel()** with explicitly localized arguments instead.

Services

The API involved in vending services has changed in PR2. The need for two names to resolve a service provider has been removed. In PR1, services were advertised in the Info.plist using a combination of NSExecutable, and NSProviderName. The provider name is now obsolete, so you simply advertise a single name under the entry NSPortName. This entry has the same meaning as in 3.3 services. Usually NSPortName will be the name of your application as NSExecutable was (e.g. "Webster"). The following API changes have also been made:

· **registerServiceProvider:withName:** has been obsoleted. Use **setServicesProvider:**.
· **unregisterServiceProviderNamed:** has been obsolete. Use **setServicesProvider:nil**.

Two new functions, **NSRegisterServiceProvider()** and **NSUnregisterServicesProvider()** can be used to register service providers under a given name. These functions should only be used by service providers not creating an application object (filter services often fall into this category). The name argument should be the same as that specified by the NSPortName entry of the Info.plist. See the Services documentation for more details.

NSWindow

The following new methods control the resizing behavior of the window. The first pair are used to make a window resize in fixed increments. The second pair are used to make a window resize such that it maintains an aspect ratio.

```
- (void)setResizeIncrements:(NSSize)increments;
- (NSSize)resizeIncrements;
- (void)setAspectRatio:(NSSize)ratio;
- (NSSize)aspectRatio;
```

The following new methods provide an OpenStep alternative to the NEXTSTEP-specific feature of instance drawing. The first method saves away a part of the window's image. Typically after this step, some temporary drawing is done. The second method restores the previously saved image, undoing any drawing that has happened since it was saved. The third method releases the memory used to hold the saved image.

```
- (void)cacheImageInRect:(NSRect)aRect;
- (void)restoreCachedImage;
- (void)discardCachedImage;
```

The **fax:** method has been removed from the OpenStep specification, and is now specific to the Mach platform.

A Windows-specific method has been added to allow access to the Windows window handle of an NSWindow object. This will only be of interest to developers calling the Win32 API directly.

```
- (void * /*HWND*/)windowHandle;
```

NSView

The following new method removes a view from its view hierarchy, without marking that the now exposed region in its superview needs redisplay. This can be useful when a view is temporaily swapped in so as to draw something on behalf of its superview.

```
- (void)removeFromSuperviewWithoutNeedingDisplay;
```

The following method was added in order to preserve the utility of panels that "become key only if needed" (the Font Panel, for example). This feature was defeated by the advent of increased keyboard accessibility to the UI, as nearly all widgets now accept becoming the first responder, which meant the panel would become key almost no matter where the user clicked. The following method is implemented by a widget to return YES if clicking on it should cause one of these panels to become key (which is the same role **acceptsFirstResponder** used to play in these panels).

```
- (BOOL)needsPanelToBecomeKey;
```

The **fax:** method has been removed from the OpenStep spec, and is now specific to the Mach platform.

The following API was removed because it was unused in any of the OPENSTEP products.

```
@interface NSView(NSRIBPrinting)
- (BOOL)canPrintRIB;
@end

typedef enum _NSPosition {
NSNoPosition = 0,
NSLeft = 1,
NSRight = 2,
NSTop = 3,
NSBottom = 4
} NSPosition;
```

A new method has been added to NSView, which is to be overridden by subclassers to find when their

view is installed in a new superview.

```
- (void)viewWillMoveToSuperview:(NSView *)newSuperview;
```

Two new display methods have been added to round out the existing set.

```
- (void)displayIfNeededInRect:(NSRect)rect;
- (void)displayIfNeededInRectIgnoringOpacity:(NSRect)rect;
```

The **NSViewBoundsChangedNotification** notification present in PR1 has been added to the OpenStep spec.

Updating in NSApplication, NSWindow and DPSClient

Various updating mechanisms in the Application Kit are now driven by a new Foundation feature, where NSRunLoop will perform selectors registered by clients in a given order during it's next cycle. (See **performSelector:target:argument:order:modes:** in NSRunLoop.) The following constants represent these uses within the Application Kit:

NSUpdateWindowsRunLoopOrdering (500000)
All Windows are sent the update message. This is also the time when menu items are enabled and disabled.

NSDisplayWindowRunLoopOrdering (600000)
All Windows holding Views needing redisplay are given the chance to redraw.

NSResetCursorRectsRunLoopOrdering (700000)
If needed, cursor rectangles are reestablished.

DPSFlushContextRunLoopOrdering (800000)
The IPC channel to the Window Server is flushed, ensuring any buffered data is executed.

NSResponder

The **insertNewLine:** method was renamed to **insertNewline:**.

NSApplicationMain

The AppKit now provides a function NSApplicationMain() to take care of the initialization and startup of your application. This function is declared in NSApplication.h. Because of this, ProjectBuilder will now generate a trivial main function for your application:

```
#import <AppKit/NSApplication.h>

int main(int argc, const char *argv[]) {
NSApplicationMain(argc, argv);
}
```

Although developer's should not need access to the body of NSApplicationMain(), it is documented here in the rare case that it is necessary. If at all possible, avoid copying this code, as doing so may prevent your application from automatically inheriting features added in future releases.

```
int NSApplicationMain(int argc, const char *argv[]) {
NSAutoreleasePool * pool = [[NSAutoreleasePool alloc] init];
NSDictionary *info = [[NSBundle mainBundle] infoDictionary];
NSString *principalClassName = [info objectForKey: @"NSPrincipalClass"];
NSString *mainNibFile = [info objectForKey: @"NSMainNibFile"];
```

```
if (principalClassName) {
Class principalClass = NSClassFromString(principalClassName);
if (principalClass) {
[principalClass sharedApplication];
if ([NSBundle loadNibNamed: mainNibFile owner: NSApp]) {
[pool release];
[(NSApplication *)NSApp run];
[NSApp release];
exit(0);
}
else NSLog(@"Unable to load nib file: %@, exiting", mainNibFile);
}
else NSLog(@"Unable to find class: %@, exiting", principalClassName);
}
else NSLog(@"No NSPrincipalClass specified in info dictionary, exiting");
[NSApp release];
[pool release];
exit(1);
return 0;
}
```

NSHost

NSHost (or NXHost)'ing is supported only between OPENSTEP for Mach machines or from NEXTSTEP 3.x machines to OPENSTEP for Mach. You cannot run an OPENSTEP application NSHost'ed to a 3.x machine. NSHost'ing is also not supported on OPENSTEP for Windows.

ObjectLinks

ObjectLinks have been removed from the OpenStep specification, and in general the feature is not supported in OPENSTEP for Mach or Windows. The exception is that the following subset of the API may be used on either platform to walk through the linked data from documents written in NEXTSTEP 3.X:

```
@interface NSDataLinkManager : NSObject <NSCoding> {
- (id)initWithDelegate:(id)obj fromFile:(NSString *)path;
- (NSEnumerator *)sourceLinkEnumerator;
- (NSEnumerator *)destinationLinkEnumerator;
@end

@interface NSDataLink : NSObject <NSCopying, NSCoding>
- (NSArray *)types;
- (NSSelection *)sourceSelection;
- (NSSelection *)destinationSelection;
- (NSString *)sourceFilename;
- (NSString *)currentSourceFilename; - (NSString *)destinationFilename;
- (NSString *)sourceApplicationName;
- (NSString *)destinationApplicationName;
- (NSDataLinkManager *)manager;
- (NSDate *)lastUpdateTime;
- (NSDataLinkNumber)linkNumber;
- (NSDataLinkDisposition)disposition;
@end

@interface NSSelection : NSObject <NSCopying, NSCoding>
+ (NSSelection *)emptySelection;
+ (NSSelection *)allSelection;
+ (NSSelection *)currentSelection;
- (NSData *)descriptionData;
- (BOOL)isWellKnownSelection;
@end
```

Note that this API is a subset of the previously provided ObjectLinks API, with one exception: The **currentSourceFilename** method has been added to NSDataLink to allow the application to query the current location of the source file (whereas the **sourceFilename** method returns the original name).

-NSShowPS

On Windows NT, when apps are run with the arguments "-NSShowPS YES", they will produce a dump of their PostScript output in the file **$TEMP\\showps.txt** (where $TEMP is an environment variable usually containing "C:\\temp".

NSColor

The following methods have been added to NSColor:

```
@interface NSColor (NSDynamicSystemColors) // OpenStep/Mach: Windows Name:
+ (NSColor *)controlShadowColor; // darkGrayColor COLOR_3DSHADOW
+ (NSColor *)controlDarkShadowColor; // blackColor COLOR_3DDKSHADOW
+ (NSColor *)controlColor; // lightGrayColor COLOR_3DFACE
+ (NSColor *)controlHighlightColor; // lightGrayColor COLOR_3DLIGHT
+ (NSColor *)controlLightHighlightColor; // whiteColor COLOR_3DHILIGHT
+ (NSColor *)textColor; // blackColor COLOR_WINDOWTEXT
+ (NSColor *)textBackgroundColor; // whiteColor COLOR_WINDOW
+ (NSColor *)selectedTextColor; // blackColor COLOR_HIGHLIGHTTEXT
+ (NSColor *)selectedTextBackgroundColor; // lightGrayColor COLOR_HIGHLIGHT
+ (NSColor *)controlBackgroundColor; // lightGrayColor COLOR_WINDOW
+ (NSColor *)controlTextColor; // blackColor COLOR_BTNTEXT
+ (NSColor *)selectedControlTextColor; // blackColor COLOR_HIGHLIGHTTEXT
+ (NSColor *)selectedControlColor; // whiteColor COLOR_HIGHLIGHT
+ (NSColor *)scrollBarColor; // grayColor COLOR_SCROLLBAR
+ (NSColor *)gridColor; // grayColor COLOR_3DFACE

@end
```

These colors should be used by developers who want to create custom controls or subclass existing controls which honor the user's color preferences. For example, where

```
PSsetgray(NX_LTGRAY);
```

was used,

```
[[NSColor controlColor] set];
```

is now used.

These colors belong to their own color space, namely:

```
extern NSString *NSDynamicSystemColorSpace;
```

Since these colors may change dynamically, they do not respond to the component accessor methods declared in NSColor.h. To extract the components of a system color, you must use NSColor's **colorUsingColorSpaceName:** method to convert the color to a color space known to respond to the component accessor methods you need.

The following notification has been added which is sent when the system colors have been changed (such as through a system control panel interface):

```
extern NSString *NSSystemColorsDidChangeNotification;
```

The default **NSCMYKAdjust** is now YES by default. This basically enables the WindowServer's ability to use an enhanced algorithm for rendering device-dependent CMYK colors on an RGB device, resulting in a greater accuracy in the on-screen appearance of CMYK colors.

Applications can turn this off by registering this default with a NO value at startup time.

Platform specific resources

Under PR1 and PR2 including platform-specific versions of resource files (nibs, for instance), required

Makefile kludgery and/or source changes. This is no longer necessary.

NSBundle has been changed so that when it fetches a resource, it will look in the directory where the resource was found one additional time to check for a platform-specific version. The platform specific versions are indicated by appending "*-platformname*" to the base name of the resource. Valid platform names include **winnt** and **nextstep**.

For example, to include a Windows-specific version of Doc.draw in your project, simply add it as Doc-winnt.draw. The call [bundle pathForResource:@"Doc" ofType:@"draw"] will find the latter under OPENSTEP for Windows. Similarly a Windows-specific version of Edit.nib can be added as Edit-winnt.nib.

Note that ProjectBuilder also provides ways to specify platform-specific app and document icons, paths, and build options.

NSMenu

The OpenStep spec was amended to make NSMenu a subclass of NSObject, not NSPanel, and to replace NSMenuCell with the NSMenuItem protocol. NeXT's OPENSTEP products also provide an NSMenuItem class which conforms to the NSMenuItem protocol.

NSMenu and NSMenuItem provide almost all of the functionality of the old classes, but some window and cell specific features are no longer available. This change was motivated by the very different ways menus are handled on different operating systems (such as Microsoft Windows). See the headers for more detail.

The NSWindow and NSView have additional support for menus to support Microsoft Windows conventions. Each NSWindow can have its own menu bar or no menu bar at all. By default NSWindow objects have the application's main menu as their menu bar while NSPanels have no menu bar. Use -[NSWindow setMenu:] to set a different NSMenu to be used as the menu bar in an NSWindow. **setMenu:** in NSWindow only has an affect in OPENSTEP for Windows since on Mach, windows do not have menu bars, but the API does exist on both platforms.

NSViews can now have menus associated with them as well. An NSView's menu is used as a contextual popup menu accessed by right-clicking the view (this should be a familiar feature to users of Windows 95). By default an NSView has no contextual menu, but some AppKit objects will provide default context menus. Currently only NSTextView (and therefore also editable controls) have a default menu, but this is likely to change. You can set a menu to be used as the context menu for a view through -[NSView setMenu:]. Context menus currently only work on OPENSTEP for Windows.

Setting a menu for either a window or view on Mach has no affect, so there is no need to do this conditionally inside an #ifdef WIN32 or anything. Context menus for views may even be supported on Mach in a later release.

Interface Style

Some aspects of the new support for multiple interface styles (or UIs) have been made public.

The header NSInterfaceStyle.h is now public and can be used by developers writing classes that need to tailor their appearance to the current interface style (usually NSControl or NSView subclasses, but not always). The function **NSInterfaceStyleForKey()** can be used to determine which style is in effect at a given time. This API should be used instead of relying on #ifdef WIN32 so that your drawing will be correct in all cases. For instance, InterfaceBuilder lets the user specify what interface style to show when editing nibs so that you can see what your interface will look like on any supported platform without actually having to be running on that platform.

The default **NSInterfaceStyle** can be used to control what style to use. By default the native interface style will be used, but you can override that with this default. Currently supported values are **Windows95** and **Mach**. Not everything can obey this setting, but most AppKit objects do.

NSPopUpButton

NSPopUpButtons no longer have NSButtonCells for items, the items in a popup now have the type **(id <NSMenuItem>)**. Also, The **-(NSMatrix *)itemMatrix** method has been replaced with **-(NSArray *)itemArray** which returns an NSArray instead of an NSMatrix.

NSButton and NSButtonCell

The **setType:** method in NSButton and NSButtonCell has been renamed to **setButtonType:**, because the old name overloaded a method inherited from NSCell.

NSMatrix

Two new convenience methods have been added to NSMatrix:

```
- (int)numberOfRows;
- (int)numberOfColumns;
```

NSSavePanel

NSSavePanel now inherits from NSObject in the OpenStep specification to gain greater portability. This means that although on Mach NSSavePanel is implemented as a subclass of NSPanel, methods inherited from NSPanel and NSWindow are not considered part of the spec. In fact, on Windows NSSavePanel is implemented as subclass of NSObject since we are using the native UI.

A new method has been added to the SavePanel to validate the visible columns. For instance, say your filtering criteria have changed. Call this method to get the correct files displayed:

```
- (void)validateVisibleColumns;
```

NSScrollView

Methods have been added to access the content view of the ScrollView. The content view is the scroll view's clip view:

```
- (void)setContentView:(NSClipView *)contentView;
- (NSClipView *)contentView;
```

Windows application lifetime issues

Applications under Windows introduce some interesting life cycle issues. One issue is that because the menus are only present inside of windows, an application with no open windows has no UI. Another issue is that when you double-click a file, Windows generally starts a fresh copy of the associated application to open it even if there's another copy already running. In OPENSTEP we have addressed these issues by defining some default behaviors and providing some new API to ensure that developers can control the behaviors if necessary.

By default, on Windows, an Application will terminate when the last menu-bearing window is closed. In general, this is the right thing to do. Sometimes, however, you may need to do something different. A new NSApplication delegate message has been added to allow you to override this default behavior. When NSApplication notices the last menu-bearing window has been closed, it will send **-(BOOL)applicationShouldTerminateAfterLastWindowClosed:(NSApplication *)sender** to the application's delegate if it responds. This message is sent on both Mach and Windows so it may be necessary to tailor your app's response for the platform. On Mach, application do not, by default, terminate when windows are closed. If you implement this method you should return YES if the

application should terminate and NO if it should not. If you return YES you will shortly receive an -applicationShouldTerminate: messageas well. If you return NO you should also have arranged for some UI to remain. If you return NO and do nothing else, you are likely to lose all UI to your app and leave the user with no way to quit or do anything else.

On the other end of the life cycle, a new Windows-only feature has been added to NSApplication. If the arguments to the application on the command line includes the argument pair "-NSUseRunningCopy YES" then the app will check to see if a copy of itself is already running, and if it is, it will hand off to the running copy and exit. Any -NSOpen or -NSPrint requests will be forwarded on to the existing copy. When file associations are made for OpenStep apps, these arguments are included in the association. Therefore, double-clicking multiple .draw documents should end up opening them in a single copy of Draw. This feature is supported through a single NSApplication method. + **(void)useRunningCopyOfApplication** is called from the default implementation of the WinMain function. Apps that never want to use this feature can implement their own WinMain and avoid calling this method, but there should be very few good reasons to want to do that.

NSPasteboard and the NSFileContentsPboardType

NSFileContentsPboardType has been modified slightly to be the same as NSFileWrapper's serializedRepresentation. We expect this change to make the type much more useful. Among other things this means that NSFileContentsPboardType and NSRTFDPboardType use identical formats. There is still a semantic difference between the two, however. NSRTFDPboardType is used only for RTFD text and it must satisfy certain constraints on the actual file contents written (eg there must be a file inside called TXT.rtf and so forth).

In support of this change, and to make it easier to use NSFileContentsPboardType in your applications, NSPasteboard has some new API for dealing with this type. In the past you had to write this type onto the pasteboard from the filesystem. And when you read it from the pasteboard you had to write it to the file system. Now it is possible to wirte this type from an NSFileWrapper instance and to read it out and get a new NSFileWrapper instance. The disk need not be involved anymore. The new API is:

```
- (BOOL)writeFileWrapper:(NSFileWrapper *)wrapper;
- (NSFileWrapper *)readFileWrapper;
```

Notification name changes

Some of the names of AppKit notifications have changed to follow the general naming guidelines.

Old Name	New Name
NSColorListChangedNotification	NSColorListDidChangeNotification
NSColorPanelColorChangedNotification	NSColorPanelColorDidChangeNotification
NSImageRepRegistryChangedNotification	NSImageRepRegistryDidChangeNotification
NSViewFocusChangedNotification	NSViewFocusDidChangeNotification
NSViewFrameChangedNotification	NSViewFrameDidChangeNotification
NSViewBoundsChangedNotification	NSViewBoundsDidChangeNotification

NSDragOperation removed

The **NSDragOperation** typedef has been removed from the API, and all uses are replaced by **unsigned int**, since the values used for this type must be often or'ed together.

NSPageLayout

NSPageLayout now inherits from NSObject in the OpenStep specification to gain greater portability. This means that although on Mach NSPageLayout is implemented as a subclass of NSPanel, methods inherited from NSPanel and NSWindow are not considered part of the spec. In fact, on Windows NSPageLayout is implemented as subclass of NSObject since we are using the native UI.

In addition, the following methods and types have been removed from the OpenStep specification, but are still available on the Mach platform:

```
- (void)convertOldFactor:(float *)old newFactor:(float *)new
- (void)pickedButton:(id)sender.
- (void)pickedOrientation:(id)sender
- (void)pickedPaperSize:(id)sender
- (void)pickedUnits:(id)sender

enum {
NSPLImageButton, NSPLTitleField,
NSPLPaperNameButton,
NSPLUnitsButton,
NSPLWidthForm,
NSPLHeightForm,
NSPLOrientationMatrix,
NSPLCancelButton,
NSPLOKButton
};
```

The **runModal** and **runModalWithPrintInfo:** methods now return NSOKButton or NSCancelButton on all platforms.

NSPrintInfo

There are two new keys available in the NSPrintInfo dictionary on the Windows platform:

```
NSPrintMustCollate
NSPrintFormName
```

NSPrintMustCollate indicates whether collation occurs when multiple copies are printed. NSPrintFormName is the form name associated with the current print request, which might be different from the NSPrintPaperName.

NSPrinter

A new method has been added to return the names of configured printers available to the system. This name can then be passed to **printerWithName:** to create an NSPrinter. If no printers are available, an empty array is returned. If an error occurs, nil is returned.

```
+ (NSArray *)printerNames
```

NSPrintPanel

The NSPrintPanel class has been removed from the OpenStep specification. In addition, these related methods in NSPrintOperation have been removed from the specification :

```
- (void)setPrintPanel:(NSPrintPanel *)panel;
- (NSPrintPanel *)printPanel;
```

NSPrintPanel is still available as a platform specific interface; however, it now inherits from NSObject rather than NSPanel.

NSPrintOperation

The following methods were added to NSPrintOperation in the OpenStep specification to allow the accessory view to be set in the print panel:

```
- (void)setAccessoryView:(NSView *)aView;
- (NSView *)accessoryView;
```

The following methods have also been added to the specification. These methods are sent to the accessory view passed to the above methods if it responds to them.

```
- (void)updateFromPrintInfo;
```

```
- (void)finalWritePrintInfo;
```

New Graphics functions

Four new functions have been added to support conformance to the Windows UI look:

```
void NSRectFillListWithColors(const NSRect *rects, NSColor *colors, int count);
```

Fills each rectangle in the array *rects* with the color whose value is stored at the corresponding location in the array *colors*. Both arrays must be count elements long. Avoid rectangles that overlap, because the order in which they'll be filled can't be guaranteed.

```
void NSDrawDarkBezel(NSRect aRect, NSRect clipRect)
```

Draws a bordered rectangle with the appearance of a pushed-in button, clipped by intersecting with clipRect.

```
NSRect NSDrawColorTiledRects(NSRect boundsRect, NSRect clipRect, const NSRectEdge *sides,
NSColor *colors, int count)
```

Draws an unfilled rectangle, clipped by *clipRect*, whose border is defined by the parallel arrays *sides* and *colors*, both of length *count*. Each element of *sides* specifies an edge of the rectangle, which is drawn with a width of 1.0 using the corresponding color from *colors*. If the *edges* array contains recurrences of the same edge, each is inset within the previous edge.

```
void NSDrawLightBezel(NSRect aRect, NSRect clipRect)
```

Draws a rectangle with the appearance of an editable text field. Only the area that intersects *clipRect* is drawn.

NSFont

The method **maximumAdvancement** was added to the API to return the advancement of the widest glyph in the given font. If the font is fixed-pitch, this is the advancement of all the glyphs.

The following API additions (which are not in OPENSTEP) allow one to get/set a list of the user's "preferred" fonts, which are checked (in order) before any other fonts when searching for a font to render some character that cannot be rendered in a pre-given or specified font. The list should typically contain fonts with different encodings and glyph complements, as available.

```
+ (NSArray *)preferredFontNames;
+ (void)setPreferredFontNames:(NSArray *)array;
```

API has also been added to access the Windows system fonts.

```
+ (NSFont *)menuFontOfSize:(float)fontSize;
+ (NSFont *)titleBarFontOfSize:(float)fontSize;
+ (NSFont *)messageFontOfSize:(float)fontSize;
+ (NSFont *)paletteFontOfSize:(float)fontSize;
+ (NSFont *)toolTipsFontOfSize:(float)fontSize;
```

The existing NSFont methods systemFontOfSize: and boldSystemFontOfSize: now return the same as messageFontOfSize: and titleBarFontOfSize: respectively. This API is valid on Mach and Windows. On Mach it returns the standard system or bold system fonts. On WIndows it will return the user's font settings from the Display options control panel if the user's chosen fonts can be supported (currently bitmap fonts are not supported, but TrueType fonts are).

NSFontManager

NSFixedPitchFontMask mask was added so that the font manager can determine whether or not a font is fixed-pitch. It may be used in trait queries.

The method **fontNamed:hasTraits:** was added to help in searching for fonts with specified traits. The available traits are specified by the trait masks.

The new method **availableFontNamesWithTraits:** uses the given mask (which may contain several one bits) in testing the available fonts. The names of all fonts matching the given bits are returned in an array.

NSInputManager/NSInputServer

The method **doCommandByName:** was removed from the API and from the NSTextInput protocol in favor of **doCommandBySelector:**. (The latter was already in the API, but has been added to the NSTextInput protocol.) Along the same lines the NSInputServer method **doCommandByName:sender:conversation:** was also obsoleted.

The method **localizedInputManagerName** replaces the method **inputManagerName**.

Dead Keys

Dead key handling in DPSClient is now off by default. The new text object and keyboard UI rely on the input management layer to simulate dead keys. NSCStringText will turn dead key handling on and off as it gains and loses first responder status. Other custom views which need dead keys to be handled by DPSClient should also use the same approach.

Help System

The AppKit's Help API has changed significantly. NSHelpPanel has been obsoleted in favor of a new class, NSHelpManager. NSHelpManager provides a more platform-independent approach to presenting help.

Previously, the only way for your application to present help was through the NEXTSTEP Help panel. Context-sensitive help and all other help for your application was displayed in the Help panel. This made sense when NEXTSTEP was the only platform for your application.

OpenStep applications, however, can run on multiple platforms, and each platform provides its own support for online help. It's important to users that applications use the native online help system (on Windows, for instance, users want the Windows help system and don't want to have to learn how to use a different help system), so NSHelpManager does not provide a comprehensive solution for presenting help. Instead, it provides cross-platform support for context-sensitive help, and allows you to present more comprehensive help (conceptual and task-based help) in any way you choose.

Context Help

Context-sensitive help (also referred to as context help) gives the user a small amount of information when they help-click on an interface item. For example, if the user help-clicks on a menu item called "Copy", they should get context help that says something like "Copies the currently selected text to the pasteboard." This text appears in a small window near where the user help-clicked, and the window disappears when the user clicks anywhere else in the application.

To provide context help for your application, follow these steps:

1. For each interface item that needs context help, create an .rtf or .rtfd file containing the text and any images you want to appear when the user help-clicks on that interface item. Try to keep the text as brief as possible and the images as small as possible.

2. If you don't need to localize your context help files, in Project Builder simply add these files to the Context Help suitcase of your project.

If you do need to localize your context help files, first copy the files into the appropriate **.lproj** directory of your project, then use Project Builder to add them to the Context Help suitcase of your project.

3. In Interface Builder, connect each interface item to its context help file by doing the following:
a. Bring up the Interface Builder inspector and choose the Help display. The Help display lists all the context help files associated with your application.
b. Select an interface item.
c. In the inspector, choose the appropriate help file.

When you compile your application, **/usr/bin/compileHelp** packages your help files into a property list named Help.plist. NSHelpManager knows how to extract context help from an Help.plist file.

Comprehensive Help

Most applications provide some form of online help that is more comprehensive and detailed than context-sensitive help, such as conceptual or task help. NSHelpManager allows you to provide this sort of comprehensive help in any way you choose. Some help authors prefer to provide comprehensive help in HTML using a World-Wide Web browser; others use tools such as Digital Librarian or Concurrence; on Windows a full-featured native help system is available. Given the availability of rich tools like Digital Librarian and HTML browsers, OpenStep on Mach no longer supplies a native help system for comprehensive help.

When the user chooses the Help menu item, NSHelpManager simply asks the Workspace Manager to open the help file you have specified for your application. That file should be the starting point of your help, and should allow users to access whatever information they might need.

To specify a help file for your application, do one of the following:

· The simplest approach, not requiring you to specify the help file anywhere in your application, is to place the help file in your app wrapper and name it after your application. If you haven't specified a help file, NSHelpManager looks in the app wrapper for an appropriately named file.

On Mach, it must be an rtf file called <appName>.rtf.

On Windows, it must be a Windows help file called <appName>.hlp.

· To specify a help file that applies to all platforms, define the NSHelpFile key in your project's CustomInfo.plist file:

```
{
NSHelpFile = "ApplicationHelp.rtfd";
}
```

If your project does not have a CustomInfo.plist, simply create one (as in the example), and add it to your project's "Supporting Files" file category. When you build your project, the contents of CustomInfo.plist will be merged into your application's Info.plist

The specified value for the NSHelpFile key can be a full or relative path, and if it is relative, it is assumed to be a bundle resource (resolved using [[NSBundle mainBundle] pathForResource: <NSHelpFile value> ofType:nil]).

OPENSTEP 4.1 Release Notes: Foundation Framework

This document contains release notes for OPENSTEP, release 4.1.
This article has been archived and is no longer updated by Apple.

About the Foundation Framework

The Foundation Framework is a library of Objective-C classes providing the infrastructure for non-user-interface object-based applications and other user-interface- and non-user-interface-based frameworks. The OPENSTEP Foundation is compliant with the Foundation portion of the OpenStep specification, and enriches OpenStep with a few extensions.

Within the Foundation are basic classes used by any Objective-C program: collection classes, Distributed Objects, persistence frameworks, Unicode and internationalization support, the foundations of event-driven programming, and facilities to insulate code from the underlying operating system.

These release notes are divided in four main sections:

· Comments on compatibility with OPENSTEP 4.0

· Notes specific to developers who have used previous releases of Foundation

· General comments on often-encountered issue areas and interesting things

· Known issues in this release

In the document below, "4.0" and "OPENSTEP 4.0" refer to all products that shipped with the 4.0 Foundation: OPENSTEP 4.0, D'OLE 4.0, and PDO 4.0 for HP-UX™ and Solaris™. "4.1" and "OPENSTEP 4.1" refers to OPENSTEP 4.1 for Mach and OPENSTEP Enterprise 4.1.

Changes and Compatibility Between OPENSTEP 4.0 and 4.1

There have been a number of changes to Foundation since the shipment of OPENSTEP 4.0, both defect fixes and a few method/function additions. These are enumerated in the section below.

Note that if your application uses API which was added between 4.0 and 4.1, your application might not run under 4.0. (If you do not want to deploy your application on 4.0, then this is not an issue.) You can catch some of the potential issues by defining the macro **STRICT_40** at compile time. This #define is similar to STRICT_OPENSTEP and is used in the Application and Foundation Kits to mark new API. Similarly, if you rely (perhaps unintentionally) on a bug fixed in 4.1, your application may not function correctly under 4.0. Make sure you test on your intended deployment platform.

A number of performance improvements were also made to Foundation between 4.0 and 4.1. Customers developing on 4.1 may find performance to be significantly worse in some cases when a project is deployed on 4.0.

Here are the feature and semantic changes to Foundation in 4.1. A list of most of the bugs fixed follows. Note that a fixed bug may also represent a semantic change from the point of view of the application.

· Some methods in 4.0 were not surrounded by **#if !defined(STRICT_OPENSTEP)** when they weren't, in fact, in OpenStep.

CLASS HEADER METHOD
NSCharacterSet NSCharacterSet.h +characterSetWithContentsOfFile:
NSConnection NSConnection.h -connection:shouldMakeNewConnection:
NSArray NSPathUtilities.h -pathsMatchingExtensions:

· These methods have been made public in 4.1. They were not public in 4.0, but existed in the 4.0 Foundation binary so there are no compatibility issues in using them. They are not in OpenStep, however.

CLASS HEADER METHOD
NSArray NSArray.h -makeObjectsPerformSelector:
NSArray NSArray.h -makeObjectsPerformSelector:withObject:
NSSet NSSet.h -makeObjectsPerformSelector:

NSSet NSSet.h -makeObjectsPerformSelector:withObject:

· These methods and functions were added to Foundation in 4.1 and are not present in the 4.0 Foundation binary. Applications which do not take some precaution in using them will not run correctly on OPENSTEP 4.0. These methods and functions are also not in OpenStep.

CLASS HEADER METHOD
NSBundle NSBundle.h +allBundles
NSBundle NSBundle.h +allFrameworks
NSFileHandle NSFileHandle.h +fileHandleWithNullDevice
NSFileHandle NSFileHandle.h -initWithNativeHandle:closeOnDealloc:
NSFileHandle NSFileHandle.h -initWithFileDescriptor:closeOnDealloc:
NSObject NSObject.h +instanceMethodSignatureForSelector:

FUNCTION HEADER
NSFrameAddress NSDebug.h
NSReturnAddress NSDebug.h
NSCountFrames NSDebug.h

· The NSUserDefaults' *_search* instance variable changed type from NSMutableArray * to NSArray *. This shouldn't be an issue, as applications should not be referencing the instance variables of NSUserDefaults directly.

· NSArray **-componentsJoinedByString:** sends **-description** to each of the array's objects and concatenates the results of that together, rather than using the objects directly. This means that this method will now operate on arrays which are composed of objects that are not NSStrings.

· The number-formatting sequences for NSCalendarDates (%d, %e, %H, %I, %j, %m, %M, %S, %w, %y, %Y) during the construction of a description can now contain formatting flags between the `%' and format code, to the extent that the string methods **+stringWithFormat:**, **-appendFormat:**, etc. understand them. Format flags are not understood during parsing from a format, however. Note that per 70220 [below], NSDateFormatters use their format string both to display the date and to parse a date from a string (which the user entered in a text field, for example), so this modest extension should not be used in the format string of NSDateFormatters. Setting the date formatter to allow natural language may obviate the issue [but may be undesirable for application reasons].

· The default uncaught exception handler now includes the name of the exception and a "backtrace" in the logged message it generates. The backtrace consists only of the return addresses on the execution stack. Additionally, on Windows™, an application exception is raised (via **RaiseException()**), which can be handled by a debugger.

· The *byref* keyword is no longer ignored when transporting NSCalendarDates (as a parameter or return value) over D.O. Thus, a parameter or return value which is declared with *byref* now results in a proxy to the calendar date instance, rather than a real calendar date instance. By default, NSCalendarDates still go over the wire bycopy. NSDates always go over the wire bycopy.

· The NSBundle class method **+pathForResource:ofType:inDirectory:** now first searches a **Resources** subdirectory of the third parameter if such a subdirectory exists. It used to examine only the directory specified in the third parameter.

· NSDate's **-dateWithCalendarFormat:timeZone:** and NSCalendarDate's **-setCalendarFormat:** now have the documented behavior with respect to the first parameter being **nil**. In 4.0, they would simply set the format to **nil**, which resulted in the various **-description** methods returning an empty string.

· NSString **-stringByAppendingPathComponent:** would refuse to append a component that began with `~' in 4.0. This was to prevent the accidental concatenation of "*~username*" onto a path, but `~' is a valid (but perhaps uncommon) first character of a file name, and that behavior was of marginal benefit, so it was eliminated.

· A missing strings file has been added to the Foundation, so in 4.1 error strings returned from the formatters (NSDateFormatter and NSNumberFormatter) will be localized.

This section contains many of the corrected defects to Foundation between OPENSTEP 4.0 and 4.1. Any of these present potential backwards-deployment issues.

Reference: 48447 [FIXED]

Platforms: HP-UX™

Issue: D.O. crashed sending some structures containing doubles

Description: D.O. would crash when attempting to send a parameter or return value which was a structure larger than 8 bytes and contained a double field.

Reference: 50670 [FIXED]

Platforms: All

Issue: NSMethodSignature's **-getArgumentTypeAtIndex:** and **-methodReturnType** returned too much information

Description: These NSMethodSignature methods returned a string which contained the type descriptors for the requested argument plus all the type descriptors for the arguments following.

Reference: 55579 [FIXED]

Platforms: All

Issue: Collections that contain themselves didn't unarchive well

Description: Unarchiving an object graph with a collection which contained itself, or contained an object which archived a reference to the collection, might have caused a program either to crash immediately when the archiving system attempted to retain it, or to crash later when a freed object was sent a message. The issue here was that the collection got retained when the recursive reference was unarchived (which is normal) before it had completed its initialization in **-initWithCoder:**, which can be an issue for objects which keep track of their own retain count (as the collection classes do).

Reference: 62019 [FIXED]

Platforms: All

Issue: Character tables were not Unicode 2.0 compliant

Description: The tables used by NSCharacterSet and shipped as resources with the 4.0 Foundation were compliant with Unicode 1.1. The Unicode 2.0 tables were not yet available at the time of release. The tables in 4.1 are Unicode 2.0 compliant.

Reference: 67201 [FIXED]

Platforms: Windows NT™

Issue: Files mapped with **-initWithContentsOfMappedFile:** could not be removed

Description: On Windows™, a file that a process has mapped cannot be removed; this is a feature of the operating system. However, even after an NSData initialized with **-initWithContentsOfMappedFile:** was deallocated, a program may not have been able to immediately remove the file. The issue was that an internal file-mapping object was autoreleased at the time the data was initialized.

Reference: 68041 [FIXED]

Platforms: All

Issue: NSString's **-stringByStandardizingPath** raised an exception in certain circumstances

Description: When passed an absolute path that ended with .., NSString's **-stringByStandardizingPath** method raised an exception.

Reference: 68223 [FIXED]

Platforms: All

Issue: **-stringByAbbreviatingWithTildeInPath** sometimes incorrectly abbreviated

Description: If the first part of a path matched the user's home directory, '~' would be substituted for that prefix, regardless of whether or not the partial component at the end of the prefix was a complete component or not. For example,

[@"/me-local/foo/bar" stringByAbbreviatingWithTildeInPath] => @"~/local/foo/bar"

if the example was executed by the "me" user whose account is "/me".

Reference: 68447, 68781 [FIXED]

Platforms: All

Issue: D.O. and archiving type signature checks didn't take structure tags into account

Description: The NeXT compiler does not include structure names in type encoding strings produced from typedefs of structures (for example, @encode(NSRange); instead, the structure tag is given as "?". This is a bug in the compiler, but one that cannot be fixed for backwards compatibility reasons. To achieve compatibility with SunSoft's compiler (which correctly emits all structure tags), a "?" as a structure tag was made to act as a "wildcard", matching anything. This is unlikely to affect user applications, but developers who construct their own type encoding strings should note this, as 4.1 will be more permissive than OPENSTEP 4.0 and NEXTSTEP was, a possible backwards-deployment issue.

Reference: 68790 [FIXED]

Platforms: All

Issue: NSConnectionDidDieNotification not sent in some circumstances

Description: If a client attempted to send a message to a server which had died before the client had processed the port death notification (which can take quite a while to arrive), an NSInvalidSendPortException would be raised rather than the NSConnectionDidDieNotification being sent.

Reference: 69174 [FIXED]

Platforms: All

Issue: Lossy conversion to NSASCIIStringEncoding more lossy than intended

Description: When NSString finds a non-ASCII character during lossy conversion to NSASCIIStringEncoding, NSString converts it to an underscore. In 4.0, when NSString found a non-ASCII character during such conversion, NSString converted the character and all the remaining characters in the string to underscores, even if they were ASCII.

Reference: 69321 [FIXED]

Platforms: Windows NT™

Issue: D.O. leaked every messaged object

Description: On NT, every object that was messaged via D.O. was leaked due to an extraneous retain.

Reference: 69471 [FIXED]

Platforms: All

Issue: NSPipe leaked file descriptors

Description: NSPipes and NSFileHandles do not take ownership of the file descriptor by default. If such an object was released without an explicit close of the descriptors, the descriptors were not recovered. The new methods **-initWithNativeHandle:closeOnDealloc:** and **-initWithFileDescriptor:closeOnDealloc:** allow for the creation of file handles which own the descriptors.

Reference: 69699 [FIXED]

Platforms: Windows NT™

Issue: **NSLog()** doesn't send duplicate output

Description: When running under a debugger, **NSLog()** would send output to the debugger and the event viewer and the standard error handle (which is often not defined for applications, but is for tools and other console-oriented processes). Now when a process is running under a debugger, **NSLog()** only sends its output to the debugger. The normal behavior of **NSLog()** is to send the string to the event viewer and standard error.

Reference: 69926 [FIXED]

Platforms: All

Issue: NSNotificationCenter sometimes sent duplicate notifications

Description: In some situations, NSNotificationCenter sent observers two (or more) copies of a single notification. This only happened to observers which were registered to receive any notification name (perhaps with restriction to particular object).

Reference: 70028 [FIXED]

Platforms: All

Issue: Fault objects could not forward messages

Description: EOFault would cause an unrecognized selector exception rather than causing **-forwardInvocation:** to be invoked on the faulted object when the fault was sent a message that the faulted object did not understand (in other words, an object faulted would not get an opportunity for forward an unknown selector). Faulted objects which wish to forward a message which may cause them to be faulted should override the new NSObject class method **+instanceMethodSignatureForSelector:** to return an NSMethodSignature for the eventual target of the forwarded message. See the subsection *Forwarding Messages in OpenStep* in the *General Comments* section below.

Reference: 70220 [FIXED]

Platforms: All

Issue: NSDateFormatter didn't convert input in the same way as output

Description: NSDateFormatters did not use the output format string to parse user-entered strings, so in most cases strings could not be entered in the same format in which they were displayed. Now a date displayed with "%m/%y" (for example) can also be entered in that format.

Reference: 70323 [FIXED]

Platforms: All

Issue: NSDateFormatter does not allow empty string

Description: Once the user had begun typing in a text field that had a date formatter, the user could not leave the field without entering a valid date; in particular, the user could not leave the field empty. Empty is now valid, and the date formatter produces **nil** for an empty string in its **-getObjectValue:forString:errorDescription:** method.

Reference: 70334 [FIXED]

Platforms: All

Issue: Time zones generated with wrong offset

Description: The **+timeZoneForSecondsFromGMT:** was incorrectly using the negative of the supplied parameter to generate the returned time zone. This also affected the parsing of dates where the time zone was specified with a raw GMT offset, like "-0700", but not where the time zone was a name, such as "GMT-0800" or "PST".

Reference: 70440 [FIXED]

Platforms: All

Issue: NSRunLoop incorrectly computed whether or not there was work to be done

Description: In some situations using background monitoring of file handles, NSRunLoop would not take into account the file handles in deciding whether or not it had any more input sources.

Reference: 70580 [FIXED]

Platforms: All

Issue: NSNumber hashed long long numbers incorrectly

Description: NSNumber hashed long longs by simply casting the value to (unsigned int). This caused some equal numbers to have different hash values, breaking the hash±isEqual: invariant.

Reference: 70612, 70718 [FIXED]

Platforms: All

Issue: NSDecimalNumber inaccuracies

Description: An error in the text from which the division algorithm was taken caused inaccuracies in the less significant end of the result of **-decimalNumberByDividingBy:withBehavior:** (in the fractional part, the ones, and tens digits, depending on the size of the numbers). Also, digits of precision were being lost during initialization on the less significant end of the number, and the decimal point was being incorrectly positioned in the result of **-decimalNumberBySubtracting:withBehavior:**.

Reference: 71006 [FIXED]

Platforms: Windows NT™

Issue: **NSFullUserName()** always returned **nil**

Description: The NETAPI32 DLL was not being loaded when needed. Note that this DLL is not implemented on Windows 95™, so this function will always return **nil** on Windows 95™. Applications should be prepared for a **nil** return value.

Reference: 71288 [FIXED]

Platforms: All

Issue: Issue popping initial autorelease pool

Description: A program could crash if it repeatedly created and released the top autorelease pool.

Notes for Users of Foundation Prior to OPENSTEP 4.0

There were several releases of the Foundation Framework prior to OPENSTEP 4.0. Foundation shipped with:

· NEXTSTEP 3.3
· Enterprise Objects Framework 1.0
· Enterprise Objects Framework 1.1
· Portable Distributed Objects 3.0
· D'OLE 3.5
· OPENSTEP 4.0 Prerelease 1
· OPENSTEP 4.0 Prerelease 2
· PDO 4.0 Prerelease 1

This section describes only API changes that have been made between those releases and OPENSTEP 4.0. For changes since OPENSTEP 4.0, see the section above titled *Changes and Compatibility Between OPENSTEP 4.0 and 4.1*. The semantics of many things have changed, but most not in a way that will affect programs (NEXTSTEP 3.3 Foundation-based programs and EOF 1.1 programs, being older, are more likely to be affected). Unfortunately, at this time there is no single source for information about such changes±refer to the *Foundation Framework Reference* and specific class specifications for the current behavior. This document does not describe extensions to Foundation provided by various NeXT products (for example, WebObjects or EOF).

Foundation is now packaged as a ProjectBuilder framework, and resides in **/NextLibrary/Frameworks/Foundation.framework**. The headers can be found in **/NextLibrary/Frameworks/Foundation.framework/Headers**.

All programs based upon previous version of Foundation should be recompiled (even if no conversion is necessary) to

function with this version of Foundation. Compiling against the old static "shlib" (the shared library shipped with NEXTSTEP 3.3, EOF 1.1, and PDO 3.0, and used by WebObjects) is not supported in OPENSTEP 4.0 (without EOF 1.1 installed).

This section is divided into a subsection for each of the previous releases of the Foundation Framework. There are no specific notes for Enterprise Objects Framework 1.0, Portable Distributed Objects 3.0, or WebObjects 1.0 developers; please refer to the section for Enterprise Objects Framework 1.1 developers. The API of the Foundation shipped with Portable Distributed Objects 3.0 and WebObjects 1.0 was identical to that in Enterprise Objects Framework 1.1 (other than extensions made by those products).

Notes Specific to NEXTSTEP 3.3 Developers

Items in the tables below (in the section titled *Tables Showing Foundation API Changes*) that are marked with "(NS33)" are changes made to Foundation between NEXTSTEP 3.3 and OPENSTEP 4.0. Also see the general comments in the section *Notes Specific to Enterprise Objects Framework 1.1 Developers* below. NEXTSTEP 3.3 developers should note the following additions to those comments:

· The header **NXAutoreleaseConnection.h** was not in NEXTSTEP 3.3. Comments referring to this header do not apply to NEXTSTEP 3.3 developers.

· Two additional headers, **NSLock.h** and **NSThread.h**, were not in NEXTSTEP 3.3, but are in OPENSTEP 4.0.

Notes Specific to Enterprise Objects Framework 1.1 Developers

Items in the tables below (in the section titled *Tables Showing Foundation API Changes*) marked with "(EOF11)" are changes made to Foundation between EOF 1.1 and OPENSTEP 4.0.

Some additional changes are not contained in the tables or are of particular note:

· Headers are now imported as **<Foundation/...>**, rather than **<foundation/...>**.

· The structure of imports has changed. The Foundation headers import all ANSI C headers they need and some of the Objective-C interfaces, but none of the operating system interfaces. The set of headers imported by each header has also changed in many places. Where a project was getting a header imported "for free" before, it may now need to import additional headers in order to compile.

· The header **NXAutoreleaseConnection.h** has been removed. Its contents have been moved to **NSCompatibility.h**.

· A **Foundation.h** header has been added, which includes the 15 ANSI C headers, and all Foundation headers except **NSCompatibility.h** and **NSDebug.h**.

· The top-level NSAutoreleasePool is no longer created for automatically±a program needs to create it itself. See the *Foundation Framework Reference* and the NSAutoreleasePool class specification for more information on creating autorelease pools.

· NSDictionary no longer constrains keys to be instances of NSString. Any object that meaningfully responds to **-hash**, **-isEqual:**, and **-copyWithZone:** can be an NSDictionary key.

· The name of the exception variable in the **NS_HANDLER...NS_ENDHANDLER** region has been changed from **exception** to **localException**.

· Some methods that are not in OpenStep, and were not guarded with **#if !defined(STRICT_OPENSTEP)**, now are guarded.

· NSObject no longer conforms to the NSCoding protocol. Instead, the classes that can be archived or distributed, and their subclasses, conform to the protocol explicitly.

· NSBundle's and NSNotificationCenter's instance variables are now declared **@private**.

· The type of the parameter to NSBundle's **+bundleForClass:** method changed from **id** to **Class**.

· The type of the parameter to NSValue's **+valueWithPointer:** method changed from **void *** to **const void ***.

· The typedef **NSStringEncoding** in **NSString.h** has changed from a typedef'd enumeration to a typedef'd scalar.

· The value of the enumeration constant **NSUnicodeStringEncoding** in **NSString.h** has changed from 0 to 10.

· The location of the resources has changed, and can now be found in the Foundation framework directory. If, in a previous release of the Foundation, your application was poking around in the Foundation resources, you should carefully consider why you were doing so, and stop doing it if possible.

· The declarations of the NSAutoreleasePool debugging methods and aids have moved from **NSAutoreleasePool.h** to **NSDebug.h**. Some of the methods are destined for obsolescence, and some new methods have been added.

· The header **NSObjCRuntime.h** now imports the headers **objc/zone.h** and **stdarg.h**.

· Many declarations and definitions were removed from the header **NSUtilities.h** and moved elsewhere, but all the previous material is still defined by importing **NSUtilities.h**. The headers to which things were moved are **NSEnumerator.h**, **NSObjCRuntime.h**, **NSDictionary.h**, and **NSString.h**.

Finally, the Foundation shipped with EOF 1.1 did not contain much of the functionality of the Foundation in OPENSTEP 4.0. These headers, and all the API they declare, were added between EOF 1.1 and OPENSTEP 4.0:

NSAttributedString.h NSFormatter.h NSPPL.h
NSByteOrder.h NSGeometry.h NSProcessInfo.h
NSCompatibility.h NSHashTable.h NSProtocolChecker.h
NSConnection.h NSHost.h NSProxy.h
NSDateFormatter.h NSInvocation.h NSRunLoop.h
NSDebug.h NSMapTable.h NSSerialization.h
NSDecimal.h NSMethodSignature.h NSSet.h
NSDecimalNumber.h NSNotificationQueue.h NSTask.h
NSDistantObject.h NSNumberFormatter.h NSTimer.h
NSDistributedLock.h NSPort.h NSUserDefaults.h
NSEnumerator.h NSPortCoder.h
NSFileHandle.h NSPortMessage.h
NSFileManager.h NSPortNameServer.h

The API added by these headers is not included in the tables below.

Notes Specific to D'OLE 3.5 Developers

Items in the tables below (in the section titled *Tables Showing Foundation API Changes*) marked with "(40PR1)" are changes made to Foundation between OPENSTEP 4.0 PR1 and OPENSTEP 4.0. This symbol also marks changes that apply to D'OLE 3.5 developers, with the exceptions noted below. See also the general comments in the section *Notes Specific to OPENSTEP 4.0 PR1 Developers* below.

The following are exceptions to the changes noted between OPENSTEP 4.0 PR1 and OPENSTEP 4.0, for D'OLE 3.5 developers:

· The header **NSPPL.h** isn't in D'OLE 3.5, but is in OPENSTEP 4.0. API changes referring to this header do not apply to D'OLE 3.5 developers.

· These methods were in D'OLE 3.5, but not in OPENSTEP 4.0 PR1:

CLASS HEADER METHOD
NSString NSPathUtilities.h +pathWithComponents: (+NeXT) (40PR1)
NSString NSPathUtilities.h -isAbsolutePath (+NeXT) (40PR1)
NSString NSPathUtilities.h -pathComponents (+NeXT) (40PR1)

Notes Specific to OPENSTEP 4.0 PR1 Developers

Items in the tables below (in the section titled *Tables Showing Foundation API Changes*) marked with "(40PR1)" are changes made to Foundation between OPENSTEP 4.0 PR1 and OPENSTEP 4.0.

Some additional changes are not contained in the tables or are of particular note:

· All applications, frameworks, libraries, bundles, tools, etc. compiled in PR1 should be recompiled.

· The header file **NSAccount.h** has been removed from Foundation. This header was NeXT-specific.

· The header file **NSByteStore.h** has been removed from Foundation (both from OpenStep and from NeXT's implementation).

· The import of the header **NSDebug.h** has been removed from **Foundation.h**; however, it still exists. This header contains features intended for debugging, but not for general use.

· **Foundation.h** now imports the 15 ANSI C headers (**assert.h**, **ctype.h**, **errno.h**, **float.h**, **limits.h**, **locale.h**, **math.h**, **setjmp.h**, **signal.h**, **stdarg.h**, **stddef.h**, **stdio.h**, **stdlib.h**, **string.h**, **time.h**) as a convenience.

· The header file **NSObjCRuntime.h** imported six obsolete headers (**ansi/ansi.h**, **objc/typedstream.h**, **objc/objc-class.h**, **architecture/byte_order.h**, **objc/hashtable.h**, **streams/streams.h**) in PR1. It no longer does so. This change may mean that some of these headers may need to be explicitly imported for code written on OPENSTEP 4.0 PR1 to recompile.

· A **STRICT_OPENSTEP** preprocessor guard now surrounds all API in the headers **NSDecimal.h** and **NSDecimalNumber.h**.

· The macro **FOUNDATION_EXPORT** is now always explicitly defined on Windows™ (that is, it cannot be predefined with the **-D** compiler option) in **NSObjCRuntime.h**.

· A new header and related functionality, **NSTask.h**, was added.

· See also changes noted in the section Notes Specific to OPENSTEP 4.0 PR2 Developers. All changes listed apply to OPENSTEP 4.0 PR1 developers.

Notes Specific to OPENSTEP 4.0 PR2 Developers

Items in the tables below (in the section titled *Tables Showing Foundation API Changes*) marked with "(40PR2)" are changes made to Foundation between OPENSTEP 4.0 PR2 and OPENSTEP 4.0.

Some additional changes are not contained in the tables or are of particular note. This list of changes applies to both OPENSTEP 4.0 PR1 and PR2 developers:

· The size of NSPort and NSRunLoop instances has changed. The NSPort class has become abstract and no longer has any instance variables. Applications, tools, frameworks, bundles, or libraries with subclasses of these two classes must be recompiled.

· The header file **NSPosixFileDescriptor.h** has been removed from Foundation. This header was NeXT-specific. The header **NSFileHandle.h** provides portable replacement functionality.

· A few new headers have been added. The API in these headers is not included in the tables below:

NSAttributedString.h NSFormatter.h
NSDateFormatter.h NSNumberFormatter.h
NSEnumerator.h NSProtocolChecker.h
NSFileHandle.h

· Many declarations and definitions were removed from the header **NSUtilities.h** and moved elsewhere, but all the previous material is still defined by importing **NSUtilities.h**. The headers to which things were moved are **NSEnumerator.h**, **NSObjCRuntime.h**, **NSDictionary.h**, and **NSString.h**.

· The header **NSObjCRuntime.h** now imports the headers **objc/zone.h** and **stdarg.h**.

· The type of the parameter to NSTask's **-setStandardInput:**, **-setStandardOutput:**, and **-setStandardError:** methods has changed from **NSPosixFileDescriptor *** to **id**.

· The declarations of the NSAutoreleasePool debugging methods and aids have moved from **NSAutoreleasePool.h** to **NSDebug.h**. Some of the methods are destined for obsolescence, and some new methods have been added.

· These methods are no longer declared on Windows™ platforms:

CLASS HEADER METHOD
NSDictionary NSFileManager.h -fileSystemFileNumber
NSDictionary NSFileManager.h -fileSystemNumber
NSFileManager NSFileManager.h -createSymbolicLinkAtPath:pathContent:
NSFileManager NSFileManager.h -pathContentOfSymbolicLinkAtPath:

Although they are still declared on Windows™, an application should not use the string constants **NSFileSystemNumber** or **NSFileSystemFileNumber**, either.

Notes Specific to PDO 4.0 PR1 Developers

Items in the tables below (in the section titled *Tables Showing Foundation API Changes*) marked with "(P40PR1)" are changes made to Foundation between PDO 4.0 PR1 and OPENSTEP 4.0 and PDO 4.0.

Some additional changes are not contained in the tables or are of particular note:

· The Foundation is now shipped as a shared library in PDO 4.0 for Solaris™. All applications, tools, frameworks, bundles, libraries, etc. should be recompiled to take advantage of this.

· The size of NSPort and NSRunLoop instances has changed. The NSPort class has become abstract and no longer has any instance variables. Applications, tools, frameworks, bundles, or libraries with subclasses of these two classes must be recompiled.

· The header file **NSPosixFileDescriptor.h** has been removed from Foundation. This header was NeXT-specific. The header **NSFileHandle.h** provides portable replacement functionality.

· A few new headers have been added. The API in these headers is not included in the tables below:

NSAttributedString.h NSFormatter.h
NSDateFormatter.h NSNumberFormatter.h
NSFileHandle.h NSProtocolChecker.h

Tables Showing Foundation API Changes

There are four tables that list the API changes between previous versions of Foundation and the version of Foundation in OPENSTEP 4.0. The first table lists general changes to API elements (classes, macros, functions, constants, and so on) except methods, the second table lists the changes to the set of methods offered by the classes in Foundation, the third table lists changes to the return values of methods (for methods that didn't change name, which are listed in the second table), and the fourth table lists changes in the location of declarations. Other miscellaneous changes that weren't described well in table format are given in the sections above.

Changes are noted from the perspective of a developer who used a previous release looking to port their Foundation-based code to OPENSTEP 4.0 (and not through any intermediate releases). For instance, changes that are marked as having been made between OPENSTEP 4.0 PR1 and PR2 do not necessarily apply to NEXTSTEP 3.3 developers (for example, an API might have been added for OPENSTEP 4.0 PR1, but removed for OPENSTEP 4.0 PR2).

The rows in the tables are marked with various symbols in the rightmost column. One set of symbols describes between which releases and OPENSTEP 4.0 the change was made:

SYMBOL MEANING
(NS33) Change occurred between NEXTSTEP 3.3 and OPENSTEP 4.0
(EOF11) Change occurred between EOF 1.1 and OPENSTEP 4.0
(40PR1) Change occurred between OPENSTEP 4.0 PR1 and OPENSTEP 4.0
(40PR2) Change occurred between OPENSTEP 4.0 PR2 and OPENSTEP 4.0

The other set of symbols indicate how the API changed. Both NeXT's implementation of Foundation, and the OpenStep specification (since version 1.0 was published) have changed. These symbols attempt to describe what has happened:

SYMBOL MEANING
(OpenStep,NeXT) Generically, a change that did not add or remove API, but affects OpenStep and NeXT's implementation
(OpenStep) Generically, a change that did not add or remove API and affects OpenStep, but not NeXT's implementation
(NeXT) Generically, a change that did not add or remove API and affects NeXT's implementation, but not OpenStep

(+OpenStep,+NeXT) Was in neither OpenStep nor NeXT's implementation, now in both
(+OpenStep,NeXT) Was in NeXT's implementation only, now also in OpenStep
(+OpenStep,-NeXT) Was in NeXT's implementation only, now in OpenStep only
(OpenStep,+NeXT) Was in OpenStep only, now also in NeXT's implementation
(OpenStep,-NeXT) Was in both, now in OpenStep only
(-OpenStep,+NeXT) Was in OpenStep only, now in NeXT's implementation only
(-OpenStep,NeXT) Was in both, now in NeXT's implementation only
(-OpenStep,-NeXT) Was in both, now in neither

(+OpenStep) Was in neither OpenStep nor NeXT's implementation, now in OpenStep only
(-OpenStep) Was in OpenStep only, now in neither
(+NeXT) Was in neither OpenStep nor NeXT's implementation, now in NeXT's implementation only
(-NeXT) Was in NeXT's implementation only, now in neither

Occasionally, to the right of the rightmost column is a note for removed API which names the replacement.

General Comments

Deep vs. Shallow Copies

In various places within the Foundation reference (primarily in the reference documentation for the collection classes), statements similar to the following are made in reference to ªdeep copiesº:

> ªdeepº means that all of the objects in the dictionary are copied, and all of the objects they contain are copied, and so on.

At a broad level, the above explanation is true. Strictly speaking, however, it is not and never has been. Immutable objects do a **[self retain]** when told to **copyWithZone:**. For leaf objects like NSStrings, this is quite reasonable. For collections, though, it has the following effect: as soon as an immutable collection is reached in the deep copy traversal of some object heirarchy, the immutable collection simply retains itself. Thus any mutable objects *it* might contain *are not copied.*

Foundation Examples

There are several Foundation examples in **/NextDeveloper/Examples/Foundation**.

Various examples illustrating the use of Distributed OLE and the NeXT ORB can be found on NeXTanswers. NeXTanswers can be accessed through NeXT's Web page, at http://www.next.com.

I/O Functionality

Two new Foundation classes, NSFileHandle and NSPipe, provide objects that represent open files or communications channels and support basic I/O operations. They make it easy for developers to write code that is directly portable to other platforms. The interfaces for these classes are declared in **NSFileHandle.h**. These classes replace the NSPosixFileDescriptor and NSPosixPipeDescriptor classes made available in OPENSTEP 4.0 prereleases. The differences from the predecessor classes for the most part involve naming and a refinement of semantics.

Archiving

NSUnarchivers own the objects that they decode. When an NSUnarchiver is deallocated, so are the objects that it has decoded, unless they have been retained. The following code, for example, will probably result in a decoded object being used after being freed:

```
NSAutoreleasePool *pool = [[NSAutoreleasePool allocWithZone:NULL] init];
NSUnarchiver *unarchiver = [[NSUnarchiver allocWithZone:NULL] initForReadingWithData:myData];
id object = [unarchiver decodeObject];
[unarchiver release];
[pool release];
... use or return object here ...
```

object should be retained before the NSUnarchiver is released, and probably also autoreleased if object is returned from the function or method. An exception to this are the **-decodeValueOfObjCType:at:** and **-decodeValueOfObjCTypes:...** methods. Objects "returned" from these two methods, like those returned from +**allocWithZone:** and **-copyWithZone:**, are not autoreleased, and must be explicitly released.

User Defaults

Foundation contains API (NSUserDefaults) which replaces the old defaults database suite of functions. User defaults with 4.0 applications are stored differently and in a different place than 3.3 user defaults. There is a new command-line utility called **defaults** that allows you to manipulate the new-style defaults just as **dread**, **dwrite**, and **dremove** allowed you to manipulate old-style defaults.

On Windows NT™, defaults are stored in the Windows™ registry. There is a program shipped with Windows NT™, **REGEDT32**, for viewing and editing registry entries. NSUserDefaults stores its domains and their key-value pairs under the entry **HKEY_CURRENT_USER\\Software\\NeXT\\UserDefaults**. The values are currently stored as strings in the property list format.

The command **/usr/bin/defconvert**, in OPENSTEP 4.0 for MACH, can be used to convert a user's 3.3 defaults database to 4.0-style defaults±simply run it from the command line with no parameters. This program converts all old-style defaults, even those of non-OpenStep applications, adding them to the user's new-style database. Since NEXSTEP 3.3 applications may not use the same default names after conversion to OPENSTEP 4.0, and 3.3 applications do not use the new defaults database, and increasing the size of the defaults database increases the amount of memory needed by each OpenStep application, converting an old defaults database to the new style usually provides little utility.

Errors in ASCII Property Lists

When a method like NSDictionary's +**dictionaryWithContentsOfFile:** is used to read and parse an ASCII property list from a file, parse errors and exceptions are suppressed, and **nil** is returned upon error. Sometimes a program wants to know about syntax errors in a property list, or wants finer-grained information about why a property list cannot be read and parsed. Another method, NSString's **-propertyList**, can be used for this purpose. The following example illustrates this:

```
- (id)readPropertyListFromFile:(NSString *)path mustBeOfType:(Class)targetClass logErrors:(BOOL)showErrors {
NSString *string;
id plist = nil;

string = [[NSString allocWithZone:NULL] initWithContentsOfFile:path];
```

```
if (showErrors && nil == string) {
NSLog(@"%@: string could not be read from '%@'", NSStringFromSelector(_cmd), path);
}
NS_DURING
plist = [string propertyList];
NS_HANDLER
if (showErrors) {
NSLog(@"%@: received exception while parsing: %@", NSStringFromSelector(_cmd), localException);
}
plist = nil;
NS_ENDHANDLER
[string release];
if (Nil != targetClass && ![plist isKindOfClass:targetClass]) {
if (showErrors) {
NSLog(@"%@: property list is not of desired type '%@'. It's an '%@'.",
NSStringFromSelector(_cmd), NSStringFromClass(targetClass), NSStringFromClass([plist class]));
}
[plist release];
plist = nil;
}
return plist;
}
```

Grammars for Serialization and ASCII Property List Formats

Grammars and description of the serialization (NSSerializer) and ASCII property list representation formats are available in the appendix to the OpenStep specification.

Strings which contain non-alphanumeric characters must be double quoted in property lists to ensure the entire string is parsed as one string object. Parse failures will result, otherwise.

Retain Cycles and Invalidation

The retain/release strategy used in Foundation allows an incautious programmer to create reference cycles in an object graph (that is, the graph of objects that retain one another in some manner). These cycles are self-sustaining and constitute a memory leak. The simplest example is to create a NSMutableArray instance and add it to itself. Since an array retains its objects, it retains itself independent of its normal usage. Retains are essentially distributed across the network via the Distributed Objects mechanism.

If retain cycles cannot be avoided by careful design, but are known *a priori*, the following technique can be used to recover the memory. For the objects in the cycle(s) whose retain counts are solely due to the cycle, all should be retained (perhaps in an array), each one told to release its retained objects, then all released. The action of releasing its retained objects would undoubtedly cause an object to become dysfunctional. Some objects already implement such a method by the name "-invalidate". It is a bug that neither NSObject nor the collections implement this method to facilitate cycle recovery.

More on Autoreleasing and Retaining

The following statements are false:

Returned objects are guaranteed to be valid for the scope of the current method.
Returned objects are guaranteed to be valid until the current autorelease pool is released.
Returned objects are guaranteed to be valid until the end of the current event loop.

The Foundation's retain count mechanism operates via **-retain** and **-release**. A code fragment such as:

```
id object = [collection returnObject];
```

creates a reference (in object) to the returned object, but does not increment the retain count of object. If you don't let the system know about your reference, by incrementing the retain count with **-retain**, the system can't ensure that your reference remains valid for any length of time. In practice, you can get away with such "weak references" most of the time. But the safest approach formalizes your reference to the object:

```
id object = [[collection returnObject] retain];
/* Do operations, some of which may be on 'object' */
...
/* Don't need object any longer */
[object release];
object = nil;
```

The -hash and -isEqual: Invariant

It is worthwhile to highlight an obscure requirement documented in NSObject class specification for the **-hash** method: The **-hash** and **-isEqual:** methods of a class must be defined so that if two objects are equal, their hash value is the same ([x isEqual:y] implies [x hash] == [y hash], but not the converse). This is easy to forget, but especially important to ensure when putting custom objects into some collections (such as NSSet and NSDictionary).

Forwarding Messages in OpenStep

Objects wishing to forward messages with the **-forwardInvocation:** method must also (re)implement the **-methodSignatureForSelector:** method. This is a result of the compiler not providing call stack descriptive information at each call site. Consequently, the runtime needs a source of information for how the stack frame is constructed. It needs this to build the invocation that will be supplied to the **-forwardInvocation:** method call. The **-methodSignatureForSelector:** method will need to be reimplemented to provide a method signature for selectors to which the object does not respond.

Fault objects in EOF which wish to forward messages should also override **+instanceMethodSignatureForSelector:**.

```
- (NSMethodSignature *)methodSignatureForSelector:(SEL)sel {
NSMethodSignature *result = [super methodSignatureForSelector:sel];

if (nil == result) { // must not respond to the selector, no runtime information available
result = [target methodSignatureForSelector:sel];
return result;
}

- (void)forwardInvocation:(NSInvocation *)invocation {
[invocation invokeWithTarget:target]; // let target implement methods that we do not
}
```

See the ForwardInvocation example in **/NextDeveloper/Examples/Foundation/ForwardInvocation**.

Debugging Aids

The *OpenStep Conversion Guide* describes several techniques for debugging Foundation and AppKit applications. The header file **NSDebug.h** also has some global flags, functions, and methods which may be useful. But be warned±although this header file is public, its contents are mostly unsupported, largely undocumented, and are subject to change without warning. Do not depend on API within this header for the operation of production programs.

Object Allocation Analysis

One of the useful flags defined in **NSDebug.h** is **NSKeepAllocationStatistics**, which allows you to analyze the object allocation activity in a program. The **AnalyzeAllocation** command line program can be used to analyze the output generated by running with this option enabled. You can also use the **ObjectAlloc** demo application which comes OPENSTEP for Mach and Windows to graph the object allocation activity in real time.

The +load Method

The **+load** message is sent to classes when they are added to the Objective C runtime. **+load** is usually received before **+initialize**. **+load** is not inherited by subclasses.

The order in which **+load** messages are sent to classes is unspecified (and specifically, a class's superclass is not guaranteed to have its **+load** method called before the class receives the message). Therefore, you should not use any subsystems or classes which are loaded at the same time, or more generally, which you do not know have received the **+load** message. If you do, you will probably cause execution of code which assumes that **+load** (and anything that *had* to be done in **+load**) has been previously executed.

There are two situations typically when classes are added to the runtime:
· when loaded dynamically from a bundle or framework by NSBundle
· at application launch

The restrictions on **+load** are perhaps most serious at launch time. The Foundation has classes and subsystems (as might any other library) which depend on **+load** being called before they are fully functional. For example, you should not use **NSZoneMalloc()** to allocate memory in **+load** methods which are statically linked into an application. You certainly should not create any objects.

Note that calling **+load** on a class isn't a solution (and is a generally bad idea), because that will cause **+initialize** to be sent first, which the class may not handle. Not to mention that doing so places into your code dependencies on which classes implement **+load** in a particular version of a library.

+load is not intended as a general initialization mechanism, and should only be used when absolutely necessary. Use **+initialize** for early initialization whenever possible.

Performance and NSNotificationCenter

NSNotificationCenter, although heavily optimized, by its nature can become a significant performance bottleneck if heavy use of notifications is made. The notification mechanism should be used judiciously.

NSAutoreleasePool's -addObject: Method

You should never use the NSAutoreleasePool instance method **-addObject:**. Use the **-autorelease** method, or **[NSAutoreleasePool addObject:]** to autorelease an object. Using the instance method incurs the risk of adding an object to a pool which is not the top autorelease pool, a semantically suspect operation, since the autorelease pool model is one of a (per-thread) stack of pools. OPENSTEP 4.0 does allow you to add objects to an autorelease pool that is not the top pool, but be warned that it is a much more expensive operation (and always will be) than adding an object to the top pool.

Frameworks as NSBundles

Frameworks are a specialized form of bundle. An application can statically link against a framework at compile time (like a library), or dynamically load a framework (like a bundle) at runtime. However, as a specialized type of bundle, there are some constraints placed on frameworks:

· A framework must have a **.framework** extension

· The name of the executable code of a framework must have the same name as the framework directory, minus the **.framework** extension. For example, the file name of the executable code for the framework **MyFramework.framework** must be **MyFramework** (or on Windows™, **MyFramework.dll**).

· On Windows™ only: The framework directory must be stored in a directory called **Frameworks**. The executable code (.dll) must be stored in a directory called **Executables** that has the same parent as the **Frameworks** directory. If the framework is statically linked into applications, the **Executables** directory (full path) should be in the PATH environment variable. (On other OPENSTEP platforms, the executable code file is stored within the framework directory, like a bundle.)

How NSBundles Search for Resources

The algorithm that NSBundles use to find resources has changed somewhat from that of NXBundles, and there are changes to the structure of bundles themselves. A bundle's resources are now stored in a directory call **Resources** within the bundle directory. Within the **Resources** directory are the non-localized resources and the localized resource directories (**English.lproj**, **Swedish.lproj**, etc., as with NXBundle). The addition of the **Resources** directory is primarily a way to simplify Framework versioning. Other changes have been made to reduce the amount of computation required to find resources.

Suppose we are searching for the resource with name **Main** and type **nib**. The bundle's resource path, the "top level", is searched first, for the file **Main.nib**. If the file is not found there, each of the language subdirectories are each searched, in the user's preference order. This is a change from NXBundle's behavior, where the language subdirectories were searched first. This change means that the localized version of a resource that also exists at the top level will not be found, but the top level one will be. All non-localized resources should be placed in the top level, and no localized resources should exist at the top level.

When a resource is found, the algorithm checks to see if a resource of the name **Main-*$(PLATFORM_OS)*** of type **nib** exists. ***$(PLATFORM_OS)*** represents the **make** variable of the same name, and takes on the same values that the **make** variable takes on at compile time. For example, on Windows™, during a project build, ***$(PLATFORM_OS)*** in the **Makefile.postamble** will have the value "winnt". When **Main.nib** is found in a directory, the search algorithm does one final check to see if **Main-winnt.nib** exists in that same directory. If it does, the search algorithm returns the path to that resource; if it does not, the search algorithm returns the path to **Main.nib**. Note that for **Main-winnt.nib** to be found, a file named **Main.nib** must exist in the same directory; this also applies within each language resource directory. It is expected that a developer will choose one of the platform-specific versions to name without this ***$(PLATFORM_OS)*** suffix, and give the other platform-specific versions of the resource extended names. The values that ***$(PLATFORM_OS)*** can take on are currently "winnt" (on OPENSTEP for Windows™), "nextstep" (on OPENSTEP for MACH), "hpux"(on PDO for HP-UX™), and "solaris" (on PDO for Solaris™).

Another way to accommodate platform-specific resources is by using the **inDirectory:** parameter of the resource-searching methods. The **inDirectory:** parameter is primarily intended to facilitate the collection of resources of a common type or purpose into a single directory; for example, all images could be put into a directory called **Images** within the resource directory. (Note that the AppKit's **+imageNamed:** method in NSImage does not support searching arbitrary directories for images.) As such, the **inDirectory:** parameter can be used to manage platform-specific resources. This is less "automatic" however, and requires the developer to specify the name of the platform-specific directory as well as replicate the required resources and language projects within that directory. The ***$(PLATFORM_OS)*** mechanism described above is simpler to use, particularly if the number of platform-specific resources is small.

Using API not in OpenStep

Many new methods and classes were added for 4.0 and some new methods for 4.1, many outside the purview of the OpenStep specification. To restrict those that are defined to the methods and classes in OpenStep, add the flag **-DSTRICT_OPENSTEP** to the **OTHER_CFLAGS** variable in the project's **Makefile.preamble**.

The Pointer Returned from malloc()

Asking **malloc()** for a block of memory that is close to the size of a page will give you a pointer for which NXZoneFromPtr() returns NULL. This is not a bug; blocks of memory allocated from **malloc()** do not necessarily come from a zone.

Known Issues in OPENSTEP 4.1

This section documents many of the known issues with Foundation in OPENSTEP 4.1.

Issue: Incorrect behavior when copying NSMutableDictionaries.

Description: According to the OpenStep specification, when you send **copy** or **copyWithZone:** to an NSMutableDictionary you should get back a deep immutable copy. This was the behavior implemented in OPENSTEP 4.0. However, in OPENSTEP 4.1 (Windows NT, Mach, and PDO platforms) what you get back is a shallow immutable copy<the objects in the dictionary are merely retained instead of being copied.

This change in behavior can have subtle effects within any code that copies NSMutableDictionaries. For example, suppose you have a mutable dictionary populated with objects, and you create a copy (which should be a deep immutable copy). If you then modify one of the objects that you had put into the original dictionary, the modified object will appear in the copy of the dictionary as well as in the original. *This bug means that a copy of a dictionary can change out from under you unexpectedly* (see "Deep vs. Shallow Copies" under General Notes, above, for an explanation of when you can *expect* copies of dictionaries and other collection classes to change out from under you). In an application, you might see no change, incorrect operation, or a crash as a result. Because it doesn't always crash your applications, and because it manifests itself in a number of different ways, this bug can be particularly difficult to detect.

In the next release of OPENSTEP, this behavior will be changed back so that it once again matches the specification. We are currently evaluating a possible patch to correct the behavior in systems running OPENSTEP 4.1.

Workaround: While you may not be able to alter the way that libraries you link against are written, in your own code you can work around this bug simply by avoiding the use of either **copy** or **copyWithZone:** with NSMutableDictionaries. The easiest way to do this is to use the undocumented method **initWithDictionary:copyItems:**, as shown here:

[[NSDictionary allocWithZone:NULL] initWithDictionary:*original* copyItems:YES]

initWithDictionary:copyItems: will be public in the next releases of OPENSTEP Enterprise and OPENSTEP for Mach. This method only makes sense when you know you have a dictionary object, but that's often the case (**isKindOfClass:** can be used for testing this). Note that **initWithDictionary:copyItems:** isn't part of the OpenStep specification.

Issue: NSInvocation always retains the return value

Description: NSInvocation always retains object return values. This can cause issues if the return value of a method is not a fully initialized object. Only **+alloc** and **+allocWithZone:** return uninitialized objects, so this is only an issue if you are using invocations to send either of those methods to a class object. If you write your own methods which return objects which are not fully initialized, you should avoid sending those messages with an NSInvocation or over Distributed Objects.

Issue: NSArchiver tracks **char *** pointers as equivalent to their contents

Description: During archiving, NSArchiver keeps track of the **char *** strings it has seen by the address passed in for encoding. If one uses the stack or **malloc()** to construct a **char ***, then encodes it using the "*" type primitive (or **@encode(char *)**), the archiver only remembers the stack/malloc address, assuming it has constant contents.

Workaround: Do not archive **char *** strings from the stack. Do not mutate or free malloc'd **char *** strings during archiving.

Issue: Proxies cannot be notification observers unless they are retained

Description: Because NSNotificationCenter does not retain observers, registering an observer with a remote NSNotificationCenter (the observer would be a proxy in the remote process) will eventually cause a crash of the remote process when it tries to message a freed object, unless the remote process explicitly retains the proxy. This situation is a bit arcane, but the same type of issue can happen with other objects that don't retain objects that they know about.

Workaround: Use an explicit protocol to tell the server (the process vending the notification center) to register and unregister an observer. The server then retains and registers the observer with the vended notification center, and unregisters and releases the observer when you tell it to do so. (If you don't include the unregister half of the protocol, the object will never be released.)

Issue: No way to get list of non-defaults command-line arguments

Description: In NEXTSTEP 3.3 (and earlier releases), command-line arguments that looked like defaults were removed from NXArgv. The array returned by **[[NSProcessInfo processInfo] arguments]**, NXArgv's replacement, however, contains all of the command-line arguments.

Workaround: Code that expected defaults options to have been stripped from NXArgv will have to be rewritten to skip default option names and their values, or the arguments array will need to be processed to remove them before using it. The **NSArgumentDomain** dictionary can be retrieved from the standard user defaults instance to find out what NSUserDefaults interpreted as a default option.

Platforms: Mach, HP-UX™, Solaris™

Issue: The main bundle can be allocated with the wrong directory

Description: If an application is not launched with a full path, NSBundle attempts to create the main bundle instance with the current directory. If the application is launched from the command-line without a full path, and the application is not in the current directory (but found via the shell path), the main bundle will not be created, and the **+mainBundle** method will always return **nil**. This will also be an issue if the application is launched without a full path and changes its current working directory before the **+mainBundle** method is first sent. The Workspace Manager always launches applications as a full path, so this is not an issue for applications launched with Workspace Manager.

Workaround: Launch the application with the full path; launch the app from the directory in which it exists (but not within an **.app** wrapper); create the main bundle instance before changing directories (if applicable); or within the app, change the working directory to the directory in which it lives and allocate the main bundle.

Issue: Changed defaults don't appear sometimes to have taken affect

Description: The default NSUserDefaults domain search order places the NSArgumentDomain before the application's domain. This is usually desirable for reading defaults, but may not be if you set/change default values. If you set a value for a default that was passed as an option on the command-line, the value is correctly set/changed in the application's domain, but **-objectForKey:** will still return the value found in the NSArgumentDomain, because by default it is searched first.

Workaround: There are various workarounds depending upon the application and its use of user defaults. The following options are relative to a particular NSUserDefaults instance (that is, if you create multiple user defaults instances, you'd have to do the workaround for each individually).

1. Remove the NSArgumentDomain from the search list, perhaps after adding any keys it contains to the registration domain; command-line specified defaults will not be found, or not have priority over same-keyed defaults in the application's domain, however.

2. Move the NSArgumentDomain after the application's domain; command-line specified defaults will not have priority over same-keyed defaults in the application's domain, however.

3. Each time you set a default value, set it in the argument domain (difficult and not worth the trouble).

4. Best solution: Create a subclass of NSUserDefaults. For each defaults instance created, create a new volatile domain, tell the instance about it (**-setVolatileDomain:forName:**) perhaps calling it "ChangedDefaults" (don't give it a name beginning with "NS"!), and insert it first in the domain search list of the new defaults instance. Override the **-setObject:forKey:** and **-removeObjectForKey:** methods to set/remove the value in the "ChangedDefaults" volatile domain, and then call **[super ...]** to do the same for the application domain. The following code illustrates what these override methods might look like:

```
- (void)setObject:(id)value forKey:(NSString *)defaultName {
NSDictionary *changedDomain;
id oldValue;
[super setObject:value forKey:defaultName];
changedDomain = [self volatileDomainForName:@"ChangedDefaults"];
oldValue = [changedDomain objectForKey:defaultName];
if (![oldValue isEqual:value]) { // Something to do
NSMutableDictionary *newDomain;
newDomain = [[NSMutableDictionary allocWithZone:[self zone]]
initWithDictionary:changedDomain];
[newDomain setObject:value forKey:defaultName];
[self setVolatileDomain:newDomain forName:@"ChangedDefaults"];
[newDomain release];
}
}

- (void)removeObjectForKey:(NSString *)defaultName {
NSDictionary *changedDomain;
id oldValue;
[super removeObjectForKey:defaultName];
changedDomain = [self volatileDomainForName:@"ChangedDefaults"];
oldValue = [changedDomain objectForKey:defaultName];
if (oldValue) { // Something to do
NSMutableDictionary *newDomain;
newDomain = [[NSMutableDictionary allocWithZone:[self zone]]
initWithDictionary:changedDomain];
[newDomain removeObjectForKey:defaultName];
[self setVolatileDomain:newDomain forName:@"ChangedDefaults"];
[newDomain release];
}

Issue: NSBundle doesn't load _profile and _debug binaries in bundles

Description: NSBundle does not attempt to load code from debug or profile versions of their binary code, which the makefiles give the _debug and _profile suffixes, respectively. If the non-debug/non-profile binary doesn't exist in the bundle, no code will be loaded. NSBundle doesn't care how the binary has been compiled, it just only looks for the file with the name given by the **NSExecutable** key in the **Info.plist** file in the **Resources** directory.

Workaround: [Mach, Solaris™, HP-UX™]: Create a symbolic link named without the _profile or _debug suffix to the _profile or _debug binary at the top level of the bundle directory. OPENSTEP 4.1 Release Notes

This file contains a complete set of release notes for the following products:

· OPENSTEP Enterprise Release 4.1 (including PDO)
· OPENSTEP for Mach Release 4.1

Information specific to only one of the above products are identified in the individual note.

This file is divided into the following major sections:

· Important Notes (contains extremely important information about the release that should be read by all OPENSTEP developers and installers)
· Compiler Tools
· Compiler (OPENSTEP Enterprise)
· Compiler (OPENSTEP for Mach)
· Debugger
· Documentation
· Driver Development
· Interface Builder
· Netware
· NEXTIME Services
· PDO
· Printing
· Project Builder
· TextEdit
· True Type
· Window Server

The following topics are release noted in separate documents:

· Application Kit Framework
· Foundation Framework
· Enterprise Objects Framework

This article has been archived and is no longer updated by Apple.

Important Notes

The following notes are of particular importance, and should be reviewed by all OPENSTEP developers and installers.

Installing OPENSTEP Enterprise

· **Cannot install under directory names with spaces** (73170). Installation under any directory names or paths containing spaces will not work. For example, trying to install under **C:\\Program Files\\NeXT** will leave the installation unusable. Install OPENSTEP Enterprise only in a directory the complete path to which contains no spaces.

· The automated uninstaller included with OPENSTEP Enterprise doesn't clean up your System environment variables after a successful uninstallation and reboot. The system environment still contains OPENSTEP-specific entries for LIB and PATH. While this isn't necessarily harmful, successive install-uninstall cycles will cause your system environment to grow. To work around this issue, after uninstallation manually edit your system environment variables as described in the uninstallation section of the *OPENSTEP Enterprise Installation Guide*. (72486)

· **The new Daylight Savings Time (DST) rule in Germany isn't accounted for** (67469). In Germany the rules for ªdaylight saving timeº have changed. From now on, Daylight Savings Time ends on the last Sunday of October, instead of the last Sunday in September. Because Foundation doesn't account for this, unless you supply a new file for **/etc/zoneinfo,** all NeXT computers in Germany will use the incorrect time (including timestamps) between September 29th and October 27th.

This bug affects all customers in Europe running NEXTSTEP 3.3, NEXTSTEP 3.3risc, 3.3Patch, OPENSTEP for Mach (all versions), and OPENSTEP Enterprise (all versions). NeXT's Technical Support department has issued a patch to address this particular issue; consult NeXTanswers for more information.

Installing OPENSTEP for Mach

· **Upgrading SPARC Systems from NEXTSTEP 3.3 to OPENSTEP 4.1** At the conclusion of the upgrade process you're told to reboot your computer. On SPARC, systems, this reboot will fail and Workspace Manager will appear to be locked up. Since your system *has* been successfully upgraded, however, it's safe to reboot your SPARC system manually.

To manually reboot your SPARC, first wait for a minute or two (to allow your disk to sync up) and then press Command-NumLock. When prompted, select "r" to restart your system.

Binary Incompatibility

PDO 4.2 on Solaris is binary-incompatible with PDO 4.0 and previous PDO releases. You must re-link all executables on a PDO 4.2 system before they will run on PDO 4.2.

Known Issues in Deployed Systems

The following two issues are known to have occured in OPENSTEP Enterprise systems configured for deployment as well as for development.

Reference: 72130

Issue: Text could display incorrectly.

Description: Depending on the length of the document you have and how fast you are typing, displayed text might sometimes have issues. For instance, you might get overlapping lines or large blank areas between two lines.

Workaround: Typing will usually fix this right away. Note that in all cases, even though the display is garbled, your document is still correct, so there's no need to exit or restart the application.

Reference: 71671

Issue: "Flash active caption bar" visual warning option might cause applications to hang.

Description: If you have enabled SoundSentry (under Accessibility Options in the Control Panel under NT 4.0), and turned on the "Flash active caption bar" visual warning option, applications could hang when they attempt to beep.

Workaround: None. Use one of the other visual warning options.

New Linker

The Microsoft linker is now the default for project builds on Windows with OPENSTEP Enterprise. This linker is the same one that ships with Visual C++. For information on this linker, consult the Visual C++ documentation.

Project Builder

· **Pasting text into a .m file can cause Project Builder to crash** (73263). Pasting text starting with a tab after an unterminated comment in a source file can cause Project Builder to crash. In addition, typing an unterminated comment<a slash, an asterisk (*), and a space<and then pressing return can cause Project Builder to crash on Mach systems.

Uninstalling OPENSTEP Enterprise

The uninstaller supplied with OPENSTEP Enterprise doesn't remove OPENSTEP-specific references from your system environment variables. This can be done manually after uninstallation by simply deleting the NEXT_ROOT environment variable and removing all invalid references from both your **Path** and **Lib** environment variables.

If you would like more detailed instructions on how to make these changes, refer to the relevant step in "Uninstalling OPENSTEP for Windows" in the *OPENSTEP Enterprise Installation Guide*. Note that this guide is supplied in printed form only, and is packaged with the OPENSTEP Enterprise CD-ROM.

Compiler Tools

This file contains release notes for the 4.1 release of the Compiler Tools. It contains information about the following topics:

· The NeXT Mach-O GNU-based assemblers

· The NeXT Mach-O static link editor
· The NeXT Mach-O dynamic link editor
· Mach-O object tools (**nm**, **otool**, and so on)

Notes Specific to Release 4.1

New Features

There is only one new feature for the 4.1 release:

· The dynamic linker now has the environment variable DYLD_FRAMEWORK_PATH to better support the development of frameworks. See the man page for details.

Notes Specific to Release 4.0

New Features

Dynamically Linked Shared Libraries

The compiler tools now allow you to build and develop dynamic shared libraries and support the programs that use these libraries, including programs that use bundles. The tools to build or use dynamic shared libraries are in the 4.1 updates for the m68k, i386, sparc, and hppa target architectures.

All object files that are part of a dynamic shared library or that are to be in an executable should be compiled with the **-dynamic** flag. The **-dynamic** flag is now the default. Executables using shared libraries must also be linked with this flag when using **cc**(1) or **ld**(1) and must be using **crt1.o** (this is done automatically with **cc**(1) and the **-dynamic** flag). To build a dynamic shared library, use **libtool**(1) with the **-dynamic** option; typically you also specify the **-install_name** *library_name* option as well as other options (see the **libtool**(1) man page).

The dynamic linker is becoming more fully-featured. It contains some programmatic support for runtime loading (but as of yet no unloading or replacing).

The static link editor uses the symbol tables of dynamically-linked shared libraries to cause modules for undefined symbols to be pulled in from static libraries and to check for undefined symbols. The **ld**(1) flags for undefined checking **-undefined** {**error**, **warning**, **suppress**} can be used; the default is to treat undefined symbols as errors. This default holds for dynamically-linked shared libraries and bundles. In these cases the dependent libraries should be listed if available. If not available then **-U** *_symbol* or **-undefined** {**warning**, **suppress**} can be used until they are.

Using and Building Dynamic Shared Libraries from Project Builder

The 4.1 version of Project Builder supports a library project type which by default is a dynamic shared library and a framework project type which by default contains a dynamic shared library. Project Builder supports the use of dynamic libraries in other project types.

To build static libraries, un-comment the LIBRARY_STYLE definition in the project makefile (LIBRARY_STYLE is set to STATIC and commented out).

Tools that are complete

· The assember, link editor, and **otool** support position-independent code for the m68k, i386, sparc, and hppa architectures. The link editor, assember and **otool** fully support indirect undefined references using symbol pointers and symbol stubs. And the assembler now fully supports Mach-O files.

· The dynamic link editor now has the first level of support for runtime loading. Currently only loading of MH_BUNDLE files is supported. Comments in the header file **/NextDeveloper/Headers/mach-o/dyld.h** describe what is not yet implemented.

Tools that are not complete

· The dynamic link editor now has the first level of support for runtime loading. Currently only loading of MH_BUNDLE files is supported. Comments in the header file **/NextDeveloper/Headers/mach-o/dyld.h** describe what is not yet implemented.

· The tool **segedit**(1) does not have support for dynamic shared libraries.

The NeXT Mach-O GNU-based Assemblers

The NeXT assembler now a fully supports Mach-O files with the ability to create arbitrary sections with the **.section** and **.zerofill** directives. Contents of sections now correctly reflect the assembly code with respect to the section aligment and no unnecessary padding is added.

Major New Features

Support for position-independent code through the use of a new relocatable form of an expression: "*add_symbol* - *subtract_symbol* + *offset*" where *add_symbol* and *subtract_symbol* can be defined in different sections.

Documentation

Assembler Manual

The assembler manual has been updated to reflect support for dynamically-linked shared libraries. It contains appendices of the instructions for the i386, M68K, and PA-RISC processor architectures. An RTF version of the Assembler manual is in:

Compiler (OPENSTEP Enterprise)

This file contains developer release notes for the Windows and PDO compilers shipped with OPENSTEP Enterprise Release 4.1.

In this release, the compilers are based on the GNU C compiler version 2.7.2.

New Features

· If the name of your source file ends in **.cc**, **.cxx**, **.cpp**, or **.C**, **gcc** will attempt to compile your program with the C++ compiler. Similarly, if the name of your source file ends in **.mm** or **.M**, **gcc** will attempt to compile your program with the Objective-C++ compiler.

· The Objective-C++ compiler is now much more useable than the ones included with OPENSTEP for Windows Prerelease 3 and with PDO 4.0.

Including Windows Header Files in Objective-C Code

In general, you should be able to include any Windows header file in an Objective-C source module without issues. The System framework contains Microsoft's header files, with slight modifications to make them compatible with **gcc**. For instance, slight changes have been made for unnamed unions, Microsoft assembly, and so on. If you have issues including any of the Windows header files, try including the file **winnt-pdo.h** before the Windows header file that's causing issues.

The -Wmost Compiler Flag

The **-Wmost** compiler flag is equivalent to FSF's **-Wall**, except that it doesn't turn on **-Wparenthesis**. **-Wmost** also suppresses warning messages about inline functions and static constants that are not actually used. This flag is for internal use and is not officially supported. Its definition may change in a future release.

Known Bugs and Limitations

The following bugs or limitations are worth noting for the GNU C and C++ compilers for this prerelease.

· **Link errors on Windows NT** (69211). Programs on Windows NT must add explicit references to at least one class in each framework in order to avoid link errors at run time. For instance, you could add a function like that in the following code excerpt, which refers to classes in each of Enterprise Objects Framework's layers. Though never invoked, it forces the appropriate linking to occur.

```
#ifdef WIN32
```

```
#import <EOControl/EOControl.h>
#import <EOAccess/EOAccess.h>
#import <EOInterface/EOInterface.h>

void _referenceAllEOFrameworks()
{
[EODisplayGroup new]; // EOInterface
[EOEntity new]; // EOAccess
[EOEditingContext new]; // EOControl
}
#endif
```

If you create your project with the type "EOF Application," this code is automatically added to your project main file.

· **Don't depend on NEXT_OBJC_RUNTIME being predefined** (62096). Although the macro NEXT_OBJC_RUNTIME is predefined on the Windows NT compiler, your code shouldn't depend on this being the case, since this macro won't be predefined in future releases of the compiler.

· **Casting a receiver to conform to a protocol doesn't work** (68626). If, when invoking a method, you cast the receiver to conform to some protocol in order to make sure the compiler invokes the correct method in cases where there is more than one method with the same name, the Objective-C compiler will not pick up on the hint. The work around is to either compile your source file with the Objective-C++ compiler (use the **-x objective-c++** switch) or assign the object returned by the method invocation to some (temporary) variable that has the same type as that object.

· **Constant strings (both char * and NSString) should be 7-bit only**. Unless constant strings are 7-bit, your code will be non-portable as compilers will deal with 8-bit strings in a machine-dependent encoding.

· **Objective-C++ global constructors**. The Objective-C++ compiler sometimes ignores global constructors; they don't always get called.

· **Random name given to executable by default** (66861). If you create an executable and don't use the **-o** flag to explicitly tell **gcc** what to name it, **gcc** will most likely give it a random name.

· **Using pipes to communicate between compiler passes** (61306). The **-pipe** flag does not work.

· **-ObjC++ requires -lstdc++ when using C++ streams on PDO** (69156). When compiling C++ programs that use C++ streams with **gcc** on PDO platforms, if you specify the **-ObjC++** flag you must also specify the **-lstdc++** flag. So, for example, a program "foo" that uses **cout** (and therefore includes **iostream.h**) would be compiled using **gcc** as follows:

```
gcc -ObjC++ foo.cc -lstdc++
```

· **__declspec(dllexport) __stdcall doesn't work** (69194). On Windows NT, functions that are declared as **__declspec(dllexport)__stdcall** aren't handled properly. This may affect some Windows header files that you include in your programs.

· **The compiler sometimes tries to create a library instead of an executable** (69087). This happens on Windows NT when a function is declared as **__declspec(dllimport)** (perhaps in a header file), but the function is actually defined in the file being compiled. The workaround is to remove the offending **__declspec(dllimport)**.

· **-Wno-precomp flag isn't supported** (63746). On Windows NT and on PDO platforms, **gcc** refuses to do anything when the **-Wno-precomp** flag is specified. Currently, the precomp option isn't supported.

· **Reporting bugs** (68122). In some cases, when the compiler detects an internal error, it prints a message requesting that you send a bug report to some electronic mail address. Please disregard this message. All compiler bugs should be reported to the appropriate channels at NeXT Software.

· **cc -MM Foo.mm produces Foo.mm.o** (40491). Compiling a file that has either a **.M** or **.mm** extension with **-M** or **-MM** will produce a file whose name is the same as the source file with the addition of **.o**. The original extension is not stripped off before constructing the name of the **.o** file.

· **-traditional-cpp acts differently on Mach than on NT or PDO** (60175). On Windows NT and on PDO, **-traditional-cpp** changes the behavior of the preprocessor in the same way that **-traditional** does. This can result in compilation errors when recompiling an existing NEXTSTEP project on Windows NT or on PDO.

· **Inconsistent function declarations involving stdcall produce unexpected results** (69506). On Windows NT, if a function is forward-declared to be **stdcall** but not declared to be **stdcall** in the actual function definition, the compiler will emit code to pop the arguments off the stack, but won't adjust the function name.

· **The linker complains about objects exported as CONSTANT** (70212). On Windows NT, if you're building a framework and you create your own DEF file for it, defining exported objects as CONSTANT will produce a warning from the linker advising you to use the word DATA instead. If you substitute the word DATA for CONSTANT in your DEF file, some or all of your objects won't be exported correctly; the linker will be unable to find them. As a workaround, simply leave the declarations CONSTANT and ignore the linker warnings.

· **-static option causes linking to fail** (70326). The **-static** and **-dynamic** compiler flags are meaningless on Windows NT, and shouldn't be used.

· **Programs that use posing sometimes crash** (72283). If a program compiled with the Objective-C compiler contains an object that accesses its superclass while posing on a category, it will crash. To workaround this issue, either rewrite your code so that it doesn't do this, or compile the program with the Objective-C++ compiler (to do this, use the **-x objective-c++** switch).

· **Objective-C++ is broken in PDO on Solaris** (69089). In this release of PDO, **gcc**

doesn't compile Objective-C++ code correctly on Solaris machines. However, you can compile both Objective-C and C++ code<providing that they are in separate source files<with **gcc**.

· **Static constructors can't be used for run-time class initialization** (54831). The PDO compiler can't apply a user-defined constructor to a global or static C++ object and send an Objective-C message in the same file. To work around this issue, eliminate the constructor, the global, or the Objective-C code.

Compiler (OPENSTEP for Mach)

This file contains developer release notes for the 4.1 and 4.0 releases of the compiler. Items specific to or introduced in this release of OPENSTEP Release 4.1 are listed first, followed by items noted in earlier releases.

Notes Specific to Release 4.1

Known Bugs and Limitations

The following bugs or limitations are worth noting for the GNU C and C++ Compilers for this release.

· **Constant strings (both char * and NSString) should be 7-bit only** (52695). Unless constant strings are 7-bit, your code will be non-portable as compilers will deal with 8-bit strings in a machine-dependent encoding.

· **Missing precomps cause compiler warnings** (73313). If you only install the DeveloperLibs and EO2Developer packages for a single architecture (ªthinº), precomps won't be generated and the compiler will generate numerous warnings. While these warnings can safely be ignored, there are a couple of workarounds: either install the DeveloperLibs and EO2Developer packages for all three supported architectures (ªfatº), or run fixPrecomps manually to generate the missing precomp files. To do this, simply log in as root and type the following in a terminal window:

```
/usr/bin/fixPrecomps
```

Notes Specific to Release 4.0

In this release, the Mach compiler is based on the GNU C compiler version 2.5.8.
The compilers Windows and PDO compilers shipped with the OPENSTEP Enterprise release are based on the GNU C compiler version 2.7.2.

New Features

· **Frameworks.** You can now specify frameworks on the linker and preprocessor command

lines. The **-framework** flag is accepted by both the linker and the preprocessor, while the **-F** flag is accepted by the linker only. These flags are defined as follows:

-framework *framework-name*

Search the framework named *framework-name* when linking. The linker searches a standard set of directories for the framework. It then uses this file as if it had been specified precisely by name. The directories searched by the linker include a couple of standard system directories plus any that you specify with **-F**.

-F *directory*

Add the specified directory to the head of the list of directories to be searched for frameworks. If you use more than one -F option, the directories are scanned in left-to-right order; the standard framework directories (LocalLibrary/Frameworks, followed by /NextLibrary/Frameworks) come after.

In your Objective-C code, include framework headers using the following format:

```
#include <framework/include_file.h>
```

Where *framework* is the name of the framework (such as ªAppKitº or ªFoundationº<don't include the extension) and *include_file* is the name of the file to be included.

Known Bugs and Limitations

The following bugs or limitations are worth noting for the GNU C and C++ Compilers for this release.

· **Using -pipe** (67853). Although the compiler rarely crashes, if it does, it may generate some assembly language output before doing so. If you use the **-pipe** flag, the assembler may not be able to detect the fact that its input is incomplete. As a result, the assembler may produce an incomplete, but valid **.o** file. If you use the **make** utility to build your application, **make** will detect the fact that there was a issue during compilation. However, when **make** is subsequently invoked, it might not recompile the source file that caused the issue, and the linker will most likely complain about unresolved external symbols.

· **Reporting bugs** (68122). In some cases, when the compiler detects an internal error, it prints a message requesting that you send a bug report to some electronic mail address. Please disregard this message. All compiler bugs should be reported to the appropriate channels at NeXT Software.

Notes Specific to Release 4.0 PR2

In this release, the compiler is based on the GNU C compiler version 2.5.8.

New Features

· **Position-Independent Code Generation (PIC)**. The way the compiler generates code has changed. It now generates position-independent code by default when it builds

libraries, bundles and executables. You can control the code generation style using the **-dynamic** and **-static** compiler flags; **-dynamic** specifies that position-independent code generation is to be used, whereas **-static** specifies position-dependent code generation. For related information, see the note on drivers and kernel servers below.

· **C++ Templates**. The compiler has been updated to support C++ templates or parametrized types. For example, consider the following code:

```
#include <stream.h>
#include <String.h>
#include <SLList.h>

typedef SLList<String> StringList;
main(){
StringList listOfnames;

listOfnames.append("hello world");
cout <<listOfnames.remove_front() << "\\n";
}
```

Then the above code is built and run:

```
%> cc++ template.cc -o test -lg++
%> test
hello world
%>
```

· **Debugging features.** The compiler includes a couple new options to assist in debugging. Specify the **-H** flag on the command to have the compiler emit a listing of included header files (indented to reflect where they are included). Specify the **-dM** option after the **-E** (preprocess) option to get a listing of all macros along with their full definitions.

Changes

· **Building drivers and kernel servers**. If you are building drivers and kernel servers, be sure to include **-static** on the command line so that position-dependent code is generated. Compilation with the **-dynamic** option assumes that the dynamic link editor (**/usr/lib/dyld**) is present in the running program, and that is not the case for modules to be loaded into the kernel.

Known Bugs and Limitations

The following bugs or limitations are worth noting for the GNU C and C++ Compilers for this pre-release, since they were not mentioned in earlier releases.

· **wchar_t string literals** (38759). The compiler generates wide-character literals for the host endian-ness only. For example, if you are cross-compiling the string L"x" from m68k to i386, it will be a big endian wide string. The only workaround is not to cross-compile modules which depend on wide characters.

The GNU Source-Level Debugger

This file contains information about GDB, the GNU Debugger. For more information, see the debugging chapter in the *OPENSTEP Development Tools Reference* manual. On Mach, you may also refer to the **gdb**(1) manual page. On PDO platforms, see the **gdb** reference in **/NextLibrary/Documentation/NextDev/DevTools/Debugger.pdf**.

Notes Specific to GDB on Mach:

The **gdb** debugger in OpenStep 4.1 for Mach is based on the version 4.14 release from GNU/FSF. This brings with it many bug fixes and new features, many of which are mentioned in the debugging chapter of the *OPENSTEP Development Tools Reference* manual.

New Features

Dynamic Link-Editor Support

GDB supports debugging of dynamic shared libraries (sometimes known as Frameworks or Bundles in the OPENSTEP world). The presence of dynamic shared libraries has some impact on debugging, which is described in this section.

Debugging symbols for dynamic shared libraries are not present in the program itself. GDB obtains them when the running program attaches and links to the shared library. This means that before the program is actually running, GDB has no information about the contents of the dynamic shared libraries that it uses.

Because of this, it is not possible to set ordinary breakpoints in a shared library before that library has been attached. GDB provides a new command for this purpose, **future-break** or **fb**. If GDB cannot find the necessary symbols to resolve a **future-break** command, it defers the breakpoint and attempts to resolve it later, when new symbols from a shared library become available. Caveat: since the **future-break** command deals with names and symbols that are as yet unknown to the debugger, it cannot check spelling for you; if you make a spelling mistake, it will never be detected and the breakpoint will never take effect.

There is also an environment variable, **DYLD_LIBRARY_PATH**, which tells the dynamic link-editor where to search for dynamic libraries. This variable can be used to cause a library with debugging symbols to be linked, even though the library on the default path has no symbols. This environment can be set from within GDB by using the **setenv** command. In order to affect the program being debugged, it should be set before running the program.

The "view" interface

In prior releases, GDB supported a GUI interface that used the NEXTSTEP Edit application as a source file viewer (invoked by the **view** command). Edit has been replaced by Project Builder as the source file viewer for GDB, and the **view** command now connects GDB to Project Builder. You must start Project Builder yourself before giving GDB the **view** command (GDB will not start Project Builder automatically). Project Builder has its own user interface for interacting with GDB (see the Project Builder documentation).

Methods with Variable Number of Arguments

GDB now understands the syntax for calling a method with a variable number of arguments (for example, **[MyClass myMethod: 1, 2, 3, 4]**).

Known Issues

Known Issues with Dynamic Link-Editor Support

It has been observed that GDB sometimes hangs or crashes if you run a program that uses a dynamic shared library (Framework or Bundle), then recompile the dynamic shared library, and run the program again. If this happens to you, we recommend that you quit GDB and start a new debugging session every time you rebuild the library. You can use the **.gdbinit** file to help re-establish things such as breakpoints that you need in your debugging session.

Interrupting with ^C during Dynamic Symbol Loading

Immediately after you start your program running under GDB, the program will start to load dynamic shared libraries, and GDB will begin reading symbols from these libraries. If you attempt to interrupt GDB by typing ^C (control-C) during this process, the debugger will be left in a confused internal state from which the only known recovery is to quit the debugger and start over.

Notes Specific to GDB on Windows:

The GDB debugger for OPENSTEP for Windows is based on the version 4.15.1 release from GNU. This brings with it many, if not most of the features of debugging on UNIX and Mach, although there are inevitably some differences.

New Features

Dynamically Loaded Library (DLL) Support

GDB supports debugging of dynamically loaded libraries (DLLs). In OPENSTEP for Windows, Frameworks and Bundles are implemented as DLL's. The presence of DLLs has some impact on debugging, which is described in this section.

Debugging symbols for dynamically-loaded libraries are not present in the program itself. GDB obtains them when the running program attaches and links to the DLL. This means that before the program is actually running, GDB has no information about the contents of the DLLs that the program uses.

Because of this, it's not possible to set breakpoints or access data in a DLL before the DLL has been attached by the program. If you need to debug code in a DLL, or set breakpoints on a function or method in a DLL, you should first set a breakpoint on **main** (or some place in the program after the DLL has been attached but before the code you want to debug has been executed). Run your program up to that point. The program will load the DLL, and GDB will gain access to it's symbols, after which you should be able to set breakpoints in the DLL. If the DLL was built with the OpenStep compiler (**gcc**), and with **-g** debugging symbols, you should be able to step into functions or methods in the DLL just like ordinary

functions or methods in your program.

Attach and Detach

GDB's **attach** command works pretty much as it does on Mach. The process ID to attach to can be obtained from PVIEW, or by having the attachee call **getpid()** and output the result. However, when GDB attaches to an already-running process, it won't learn about symbols from DLLs that the process has already linked to.

The **detach** command is only partially useful at this time. **detach** will let the attached process continue to run, but a parent/child relationship continues to exist between the debugger and the detached process. Because of this, if you then quit the debugger, the detached process will also die.

When you attach to a running process, you will frequently find yourself in a non-debuggable area of code from which you cannot even get a backtrace. See the section on known issues, "Non-Debuggable Code" below for more information on this topic.

Add-Symbol-File

When GDB attaches to a running process, it does not read any symbols from DLLs that the process has previously linked itself to. If you need those symbols for debugging, you can explicitly cause GDB to load them by using the **add-symbol-file** command. This command takes two arguments: the fully-qualified filename of the DLL file, and a base address. For a DLL that you build, this base address will be the base address at which you linked the DLL plus 0x1000. Here are the base addresses to give to the **add-symbol-file** command for the major OPENSTEP DLLs:

· 0x30001000 System
· 0x31001000 nextpdo
· 0x32011000 Foundation
· 0x34021000 AppKit
· 0x38031000 NeXTApps
· 0x3A041000 DevKit
· 0x3C051000 ProjectBuilder
· 0x3C051000 InterfaceBuilder
· 0x40001000 Message
· 0x42011000 WebObjects
· 0x44021000 EOControl
· 0x46031000 EOAccess
· 0x48041000 EOInterface
· 0x4A051000 Sybase
· 0x4C061000 Oracle
· 0x4E071000 Informix
· 0x50081000 nextorb
· 0x52091000 EOModeler

Command Editing

GDB's command line history can be accessed by using the up and down arrow keys, or by using the EMACS key bindings (^P and ^N to scroll thru previous commands, ^B, ^A, ^E to move around on a line, and so on). Also, **set history expansion on** enables C-shell-like command history within GDB (**!!**, **!print** and so on). As usual, an empty newline repeats the previous command (except where specifically disabled, as with the **run** command).

Debugging Objective-C: Differences from Mach GDB

The Windows version of GDB is more of a multi-language debugger than the older GDB on Mach (especially the older version of GDB available with previous releases of NEXTSTEP). This GDB has separate features for many different languages, including Objective-C. It attempts to guess the source language by looking at the extension of the source file name ("**.m**" or "**.M**" for Objective-C). To find out what GDB's ªcurrent languageº is, type **show language**. To force the current language to Objective-C, type **set language objective-c**.

Calling Methods from GDB

To call a method in your program from GDB, use the **print**, **set**, or **call** commands with an argument that looks just like a method call in Objective C, as shown here:

```
(gdb) print [myClass showValue: 12]
```

If the method comes from a Category, you must include the category name, like this:

```
(gdb) print [myClass(myCategory) showValue: 12]
```

Listing and Setting Breakpoints on Methods

To refer to a method in a **list** or **break** command, you can give the full class and method name, including a `+' or `-' to indicate a class method or instance method. If there is a category name, you must give that too:

```
(gdb) list +[myClass init]
(gdb) break -[myClass(myCategory) showValue]
```

You can also set breakpoints or list a method just by giving a selector. If the selector is implemented by more than one class, gdb will list the corresponding methods and ask you to choose one or more:

```
(gdb) break init
[0] cancel
[1] all
[2] -[Change init] at Change.m:20
[3] -[DrawApp init] at DrawApp.m:130
[4] -[Graphic init] at Graphic.m:139
>
```

You would then enter your choice or choices at the ">" prompt.

Getting Information about Classes and Methods

GDB for Windows now has the **info classes** and **info selectors** commands. These commands accept the same regular expression language as GDB's **info type** and **info**

function commands (ie. the Unix style regular expression language). This is a change from the Mach gdb, where **info classes** and **info selectors** accept a slightly different regular expression language. For instance, to learn about class names beginning with NS (using the '^' character to designate ªbeginning withº):

```
(gdb) info classes ^NS
```

To learn about selectors, you can use the **info selectors** command. To find every selector containing the string "withObject:" you could enter:

```
(gdb) info selector withObject:
```

To learn about methods, you can use the **info function** command, which also takes a regular expression. Since the square bracket characters `[' and `]' are significant in regular expressions, you can quote them with a backward slash to prevent their being treated as special characters. To list all the methods of a class, you might say:

```
(gdb) info function \\[MyClass
```

To list all the methods whose selector ends with ªcount:º, you might say:

```
(gdb) info function count:\\]
```

If you want to know about a specific method of a specific class, but you are not sure if it belongs to a category, you could use the ª.*º wildcard sequence to stand for ªany number of any charactersº:

```
(gdb) info function MyClass.*mySelector:
```

Debugging Threads on Windows

The GDB for Windows is thread-aware. If you are debugging a multi-threaded program, you can use the **info threads** command to see a list of the currently active threads. Use the **thread** command to switch to one of the threads listed by **info threads**, giving it the number of the thread you want to debug (a small integer such as 1 or 2, not the thread ID).

When you switch threads, you will frequently find yourself in a non-debuggable area of code from which you cannot even get a backtrace. See the section on known issues, ªNon-Debuggable Codeº below.

Known Issues

Non-Debuggable Code

When you interrupt a program with ^C, attach to a running program, or switch threads in a running program, sometimes the program will be in the middle of executing Windows code that cannot be debugged. Often GDB cannot even give you a backtrace, because Windows has done something with the program stack. When this happens, if you don't want to simply let the program continue (for instance, you need to know exactly how you got to where you are), you can use the **stepi** command to step by single machine instructions until the Windows code cleans up the stack and returns, at which time you will suddenly be able to see symbols and backtraces again. GDB will notify you when you have returned to a

symbolic region (say, a function or a method) that it knows about. Usually this does not take too long; on the order of a few dozen instruction steps.

Notes Specific to GDB on PDO:

The **gdb** debugger for OPENSTEP Enterprise is based on the version 4.15.1 release from GNU. This brings with it many, if not most of the features of debugging on Mach, although there are inevitably some differences.

Debugging Objective-C: Differences from Mach gdb

The PDO version of **gdb** is more of a multi-language debugger than the older **gdb** on Mach (especially the older version of **gdb** available with previous releases of NEXTSTEP). This **gdb** has separate features for many different languages, including Objective-C. It attempts to guess the source language by looking at the extension of the source file name (**.m** or **.M** for Objective-C). To find out what **gdb**'s current language is, type **show language**. To force the current language to Objective-C, type **set language objective-c**.

Calling Methods from gdb

To call a method in your program from **gdb**, use the **print**, **set**, or **call** commands with an argument that looks just like a method call in Objective-C. For example:

```
(gdb) print [myClass showValue: 12]
```

If the method comes from a category, you must include the category name, as shown here:

```
(gdb) print [myClass(myCategory) showValue: 12]
```

Listing and Setting Breakpoints on Methods

To refer to a method in a **list** or **break** command, you can supply the full class and method name, including a + or - to indicate a class method or instance method. If there is a category name, you must give that too:

```
(gdb) list +[myClass init]
(gdb) break -[myClass(myCategory) showValue]
```

You can also set breakpoints or list a method just by giving a selector. If the selector is implemented by more than one class, **gdb** will list the corresponding methods and ask you to choose one or more:

```
(gdb) break init
[0] cancel
[1] all
[2] -[Change init] at Change.m:20
```

```
[3] -[DrawApp init] at DrawApp.m:130
[4] -[Graphic init] at Graphic.m:139
>
```

You would then enter your choice or choices at the ">" prompt.

Getting Information about Classes and Methods

gdb for PDO has the **info classes** and **info selectors** commands. These commands accept the same regular expression language as **gdb**'s **info type** and **info function** commands (that is, the UNIX-style regular expression language). This is a change from the Mach **gdb**, where **info classes** and **info selectors** accept a slightly different regular expression language. For instance, to learn about class names beginning with "NS" (using the "^" character to designate ªbeginning withº):

```
(gdb) info classes ^NS
```

To learn about selectors, you can use the **info selectors** command. To find every selector containing the string "withObject:" you could enter:

```
(gdb) info selector withObject:
```

To learn about methods, you can use the **info function** command, which also takes a regular expression. Since the square bracket characters ('[' and ']') have special significance in regular expressions, you can quote them with a backward slash to prevent their being treated as special characters. To list all the methods of a class, you might say:

```
(gdb) info function \\[MyClass
```

To list all the methods whose selector ends with "count:", you might say:

```
(gdb) info function count:\\]
```

If you want to know about a specific method of a specific class, but you aren't sure if it belongs to a category, you can use the ".*" wildcard sequence to stand for any number of any characters:

```
(gdb) info function MyClass.*mySelector:
```

Known Issues

Issues with Underscores

gdb doesn't correctly handle methods for which either the class, the category, or the selector has underscores in the name, except when the underscore is the first character of the class or selector name.

Thread Support

gdb has no support for debugging multiple threads on either Solaris or HP-UX.

Random SIGTRAPs

gdb occasionally throws random SIGTRAPs. If you verify that the instruction at the $PC is not a trap instruction, you should be able to continue by saying "signal 0" (that's a zero). This tells **gdb** to continue the child without passing any signal to it.

Documentation

This file contains release notes for the Documentation distributed with OpenStep 4.1.

Locating the Developer Documentation

All of the documentation for OPENSTEP 4.1 can be found on-line (some of the documents are supplied in printed form, as well). The easiest way to access this documentation is to open the NextDeveloper bookshelf using Digital Librarian (this bookshelf can be found in **/NextLibrary/Bookshelves**). Although the NextDeveloper bookshelf can be used directly to access the documentation, most developers prefer to create their own custom bookshelf containing just those documents of interest. Select the first entry in the NextDeveloper bookshelf, then click ªList Titlesº; the documents that are then listed detail how to create your own custom bookshelf.

In NEXTSTEP Release 3.3, as well as in prior releases, all developer documentation was located in a subdirectory of **/NextDeveloper/Documentation/NextDev**. In OPENSTEP 4.1, framework documentation has been moved to a location inside of the relevant framework. All remaining developer documentation can still be found under **/NextDeveloper/Documentation/NextDev**.

In keeping with the philosophy that all framework resources be located within the framework, framework reference documents are located in the directory **Resources/English.lproj/Documentation**, relative to the ª**.framework**º directory. So, for instance, reference documentation for the Application Kit Framework can be found in **/NextLibrary/Frameworks/AppKit.framework/Resources/English.lproj/Documentation**.

Release Notes

/NextLibrary/Documentation/NextDev/ReleaseNotes contains important information about the release that was known at the time that the OPENSTEP 4.1 CD-ROM was manufactured. Additional important information, which was discovered too late to be put onto the release, can be found on NeXTanswers. Request NeXTanswers #2455 for the location of the most up-to-date release notes for a variety of NeXT's software products.

Driver Development

OPENSTEP 4.1 cannot be used to develop Mach device drivers. Because NEXTSTEP 3.3 device drivers work on OPENSTEP 4.1 systems, we recommend that you use NEXTSTEP 3.3 Developer to create device drivers.

Interface Builder

This file contains release notes for Interface Builder distributed with OPENSTEP Release 4.1.

Notes Specific to Release 4.1

New Features

This release of Interface Builder supports these new features:

· *Context Menus*. Interface Builder on Windows NT has a context menus within editable windows and panels. A context menu is activated by clicking the right mouse button within a window or panel. In this way, operations such as Cut, Copy, and Group can be performed.

· *Interface Styles*. Interface Builder has a new preference which permits nib files to be viewed and edited in either Mach or Windows user interface style. Nib files opened after a change in the interface style preference will have the new interface style.

· *Control mnemonics.* Interface Builder enables users to set mnemonics for user-interface controls. In order to set a character in the title of a control to be a mnemonic, double-click the character while holding down the Alternate key.

· *OpenStep Compliance*. Interface Builder is OpenStep-compliant, and you can use it to create OpenStep nib files.

· *Custom Class Inspector*. You now use a new inspector display, the Custom Class Inspector, to specify a custom subclass of an object. For example, suppose you have defined a class MyButton to be a subclass of NSButton. To add an object of class MyButton to your interface, you do the following:

1. Define MyButton in the Classes view of the nib file window.
2. Drag the button from the Views palette to your interface.
3. Choose Custom Class from the pop-up list in the Inspector panel.
4. Select MyButton in the browser to set the class of the button.

Currently, this works only for NSView and NSWindow subclasses.

· *Connection Locking*. Connection locking prevents connections from being deleted when a nib file is edited. This feature is designed primarily for localization. To turn connection locking on or off, use the Preferences panel.

· *Nib Dumping.* A new tool, **nibTool**, prints the contents of a nib file in an ASCII format. **nibTool** is located in **/usr/bin**. You can easily compare two versions of a nib file if you use this tool to create ASCII representations of each. Currently, **nibTool** does not support nib files that use objects from custom palettes.

· *Typed Outlets and Actions.* The parser in Interface Builder has been improved, and many parsing bugs have been fixed. In addition, you can now specify typed outlets. Interface Builder considers any of the following to be an outlet when it appears in an interface:

```
id outlet;
id outlet1, outlet2, ...;
IBOutlet SomeClass *outlet;
IBOutlet SomeClass *outlet1, *outlet2, ...;
```

You can also specify the type of the argument to an action, and you can specify the return type to of an action to be **void**. Interface Builder considers any of the following to be an action:

```
- action:sender;
- (void)action:sender;
- action:(id)sender;
- (void)action:(id)sender;
- action:(SomeClass *)sender;
- (void)action:(SomeClass *)sender;
```

The declarations of IBOutlet are in <AppKit/NSNibDeclarations.h>.

· IB supports the new NSComboBox object. It appears on the DataViews palette.

· The date and number formatters now live on the DataViews palette, not the EOF palette.

Known Issues

These issues exist in this release of Interface Builder:

· If you are running with 8-bit color, testing your interface may cause Interface Builder to crash. After entering test interface mode, if you exit test interface mode by clicking on the close box of the last open window, Interface Builder will be `hidden' - none of your document windows will reappear. At this point, you can restore Interface Builder to its active state by restarting it from the start menu. Unfortunately, Interface Builder will be in an unstable state, and may crash after a few operations. The workaround is to always exit test interface mode via the `Exit' menu item. (72599)

· After displaying the inspector the first time, deleting a menu item or submenu may cause Interface Builder to crash. This can happen even if you close the inspector and then delete a menu item. The workaround is to either delete the menu item before you display the

inspector the first time, or to select the `Custom Class' inspector from the inspector popup before you delete the menu item. (72727)

· If you select BooksOnline from Interface Builder's Help menu on a system running Windows NT version 3.51, you'll discover that the links on the BooksOnline page appears to be broken. BooksOnline works correctly, however, if you invoke it from the OPENSTEP Enterprise program group.

· NEXTSTEP Release 2 nib files containing bitmaps unknown to the Application Kit are not loaded correctly. As a workaround, open the nib file in a Release 3 Interface Builder and save it before opening it in 4.1. For a list of bitmaps that the Application Kit supports, see the file **/NextLibrary/Frameworks/AppKit.framework/Headers/NSBitmapImageRep.h**.

· Interface Builder does not allow you to change the size of the document view when editing a ScrollView.

· The context-sensitive help links don't work for anything in the palettes window, and they don't work in the ScrollView Attributes display.

· Model files copied from a mail message are incorrectly referenced. In Interface Builder, if you drag a model file in from a mail message, it turns into an entity controller. Don't make a copy, and save the nib file. Then drag the model file from the mail message into **~/Library/Models**. Go back into the nib file and delete the combined controller/data source object. Then drag the model from **~/Library/Models** into Interface Builder. The resulting entity controller still references the model file in your mailbox.

Novell Netware

Novell Netware is not included in this release of OPENSTEP 4.1.

NEXTIME Framework

New Features in 4.0

OpenStep

The NEXTIME framework was introduced with release 4.0. It differs considerably from the architecture shipped with NEXTIME 1.0. The framework makes extensive use of the OPENSTEP Foundation classes.

NTMovieScreen

The new NTMovieScreen class provides a simple way to add movie support to applications.

An NTMovieScreen is an NSControl containing a NTMovieScreenCell in which you can display a NEXTIME movie. The user can then start and pause the movie's playback by clicking anywhere in the NTMovieScreen.

NTMovieScreenCell

NTMovieScreenCell is a subclass of NSActionCell for displaying the video data of a NEXTIME movie. Clicking the mouse within the cell's frame normally starts playback of the movie. If the movie is already playing, the click pauses the playback, so that the current video frame is displayed as a still image. The NTMovieScreenCell is normally associated with a NTMovieDocument or other object conforming to the NTMovieDocument and NTMovieDrawing protocols.

NTMovieControlView

The NTMovieControlView class provides a basic horizontal control bar to play, position, and step through movies. The view incorporates a pop-up volume control on systems with sound hardware. The class is intended to communicate with a NTMovieDocument or similar class.

NTMovieDocument

The NTMovieDocument manages a single movie, usually by displaying it in an NTMovieScreen and receiving control messages from an NTMovieControlView. Operations supported include play, pause, reset, fast forward or reverse, and step forward or backward. Notifications from the NTMovieDocument report changes in the movie's playback status and its position in time. The class provides support for editing movies from the pasteboard.

/usr/etc/showmacresources

The **showmacresources** program slightly modifies the state of the loaded Macintosh filesystem to enable or disable reporting of resource forks by the functions used to report directory contents. NEXTIME users can use this program to make finding and copying Macintosh Quicktime movie resource and data forks much easier.

showmacresources
showmacresources +

Enable reporting of resource forks on disks mounted after the command is run.

showmacresources -

Disable reporting of resource forks on disks mounted after the command is run.

The Macintosh filesystem must be loaded prior to running **showmacresources**. There are two ways to ensure that the Mac filesystem is loaded.

1) You can load the Macintosh filesystem by inserting a floppy. Simply insert a Macintosh CDROM or floppy, and, on non-NeXT hardware, click on the ªDisk->Check for Disksº Workspace menu item. Once the Workspace has found and displayed the disk, eject it. The Macintosh file system is now loaded.

2) You can load the Macintosh filesystem from a shell. To do so, run the following command as root:

```
kl_util -a /usr/filesystems/mac.fs/macfs_reloc
```

The Macintosh file system will be loaded.

If you always want to see resource forks for Macintosh files, you can modify your **/etc/rc.local** file to always load the Macintosh file system and modify it to show resource forks:

```
#
# Load Macintosh filesystem and modify to report resource forks
#
if [ -f /usr/filesystems/mac.fs/macfs_reloc -a -f /usr/etc/showmacresources ]; then
/usr/etc/kl_util -a /usr/filesystems/mac.fs/macfs_reloc
/usr/etc/showmacresources +
fi
```

Known Issues in This Release

Cursor during Movie Playback

If the cursor is placed in the movie screen area during movie playback, the cursor will disappear until moved again. When the cursor is moved across the playback area while the movie is playing, it may leave behind small squares of ªstaleº movie images which will disappear when the next key frame is drawn (usually within 1 second).

PDO

Known Issues in This Release

This section documents some of the known issues with this release of PDO. Known issues with specific portions of PDO (such as Foundation, the compiler, and so on) can be found in their own release note files.

Reference: 66188

Issue: Redefinition of MIN and MAX on HP/UX generates a warning

Description: On HP/UX, **param.h** doesn't guard against the redefinition of MIN and MAX. Since **NSString.h** indirectly includes **param.h**, if you've already imported **NSObjCRuntime.h** (which defines MIN and MAX, properly guarded against redefinition), you get a warning when **param.h** overrides these.

Workaround: Edit the copy of **param.h** that's located in **NextDeveloper/lib/gcc-lib/hppa1.1-nextpdo-hpux/2.7.2/include/sys** (relative to the location where PDO is installed), and place a guard around the MIN and MAX defines, as shown here:

```
#ifndef MIN
#define MIN(a,b) (((a)<(b))?(a):(b))
#define MAX(a,b) (((a)>(b))?(a):(b))
#endif
```

Reference: 68675

Issue: Hang while looking up connection after fork

Description: If you have a DO client which tries to look up a connection using NSConnection's **connectionWithRegisteredName:host:**, then forks a process, and then either exits or tries to look up the connection again, the client will hang. If the fork is omitted, the client won't hang.

Workaround: None.

Reference: 69152

Issue: HP-UX nmserver has issues when passing large structures

Description: On HP-UX systems, passing large structures over DO without having first defined a protocol can cause the nmserver to become non-functional.

Workaround: Use DO protocols when passing large structures over DO on HP-UX.

Reference: 69056

Issue: Multi-threaded DO example occasionally hangs on HP-UX

Description: Compiling and running the multi-threaded DO example in **/NextDeveloper/Examples/Foundation/MultiThreadedDO** occasionally results in a hang.

Workaround: None.

Deviations from the OpenStep Specification

The following items are known departures from the OpenStep specification:

· **[NSString stringByStandardizingPath]** raises when presented an absolute path ending in "**..**".

· PDO's implementation of dynamic loading of code from bundles doesn't work on either HP-UX or Solaris. This includes related functionality such as **+bundleForClass:**.

Printing

The following notes relate to printing, and augment those found in the Application Kit Release Notes.

Known Issues in This Release

Reference: 59276

Issue: Default printer in NEXTSTEP 3.3 vs. OpenStep apps

Description: Different default mechanisms are used for NEXTSTEP 3.3 and OpenStep 4.*x* applications. As a result, if you select a printer in TextEdit, it will not be the default printer in Edit.

Windows-Specific Notes

Third-party software is required to print to non-PostScript printers from OPENSTEP Enterprise applications.

Project Builder

This file contains release notes for the Project Builder application distributed with OpenStep 4.1. It includes information specific to OPENSTEP for Mach and to OPENSTEP for Windows as well as information general to both platforms.

Project Builder has undergone a radical redesign since NEXTSTEP 3.3. Its main window integrates a project browser with a full-featured code editor. You can bring up panels for building, debugging, finding information in the project, and setting project attributes. To familiarize yourself with the new Project Builder's capabilities and features, you can do one of the following.

· On Mach, choose the Help command from Project Builder's Info menu. This launches a Digital Librarian bookshelf containing the on-line book *OpenStep Development: Tools and Techniques*.

· On Windows, choose the How To command from Project Builder's Help menu. This launches a Windows Help version of the same book.

New Features for 4.1

New Makefiles

Project Builder includes new makefiles that offer several advantages over the previous ones. They:

· Build projects with lower overhead.
· Fix a number of extensibility issues.
· Allow a higher degree of parallelism with **gnumake -j**.
· Make it easier to diagnose issues.

When you first open a project that uses the old makefiles, Project Builder displays a panel that lets you :

· Convert immediately to the new makefiles.
· Keep your current makefiles.
· Defer the decision to later.

If you convert to the new makefiles, the project defines this path to them in MAKEFILEDIR:

$NEXT_ROOT/NextDeveloper/Makefiles/pb_makefiles

The original 4.0 Makefiles are located in this directory:

$NEXT_ROOT/NextDeveloper/Makefiles/project

Currently, you can override the MAKEFILEDIR attribute for your project in **Makefile.preamble** by setting it to the desired directory. Or you can edit the MAKEFILEDIR attribute in **PB.project**, but not through the user interface of Project Builder. You are strongly encouraged to convert your projects to the new makefiles if that is feasible. For instance, a new facility that automatically generates **.def** files (see below) depends on these makefiles. However, you might keep older makefiles intact for those exceptional projects that depend upon unique implementation details in the project makefiles.

Microsoft Linker

The Microsoft linker is now the default for projects on Windows built with Project Builder. This is the same linker that ships with Visual C++. For information on using the linker, consult the Visual C++ documentation. See the following item, "Automatic Generation of .def Files," for a related issue.

Automatic Generation of .def Files

On Windows, the Microsoft linker requires symbols exported from a framework DLL to be explictly specified. One way of doing this is in a **.def** file in the project (for example,

"MyFramework.def"). In prior releases, this file had to be manually created. Project Builder now generates a **.def** file for frameworks and dynamic libraries (that is, library projects producing DLLs). It re-creates the file the first time a project is built and, thereafter, updates it every time an object file changes. To get this feature, you must update to the new makefiles (See "New Makefiles," above).

If you currently have a **.def** file for a framework, and it is not highly customized, delete it and let Project regenerate it for you. Otherwise, leave it where it is. Project Builder creates a **.def** file only if there isn't one already in the project.

The **.def** file that Project Builder creates is comprehensive, so if you want to create a customized .**def** file that is a subset of it, first build your project. Then add the generated **.def** file in **derived_src** to Supporting Files in your project and edit it as necessary.

Note 1: You should use the CONSTANT keyword instead DATA in your **.def** file. The export of framework functions also requires a little extra code. For more on both of these items, see "Known Issues in this Release, " below.

Note 2: If you have prerelease versions of OPENSTEP 4.1 in which you used **Makefile.preamble-winnt** and **Makefile.postamble-winnt** for manually generating **.def** files, you can delete these files and now use Project Builder's automatic **.def** generation facility. Remember to remove all references to items involved in manual **.def** generation, particularly where your Makefiles include the platform-specific makefiles. Do this by disabling the option in your respective pûeamble and postamble files. For example:

```
#-include Makefile.preamble-$(PLATFORM_OS)
```

Specifying Installation Directories for Dynamic Libraries

On Windows, the makefiles for dynamic-library projects (that is, projects with "LIBRARY_STYLE = DYNAMIC") put the two files generated by the project in different locations. The **.dll** file is installed in INSTALLDIR and the **.lib** file is installed in the location for libraries that are imported into executable. You can specify this latter location in **Makefile.preamble** by setting IMPORT_LIBRARY_DIR to the correct path.

New Features for 4.0

Some or all of these new features may exist in the Windows version of Project Buiilder depending on its state at the time of the release:

· The new Launcher Panel allows you to run or debug executables built by the project.

· Printing is now supported.

· The Build Attributes Inspector allows you to specify OS specific values for compiler flags, linker flags, installation and build directories, and build tool.

· The Build Options panel values persist across invocations of Project Builder. The values you specify on this panel are saved per-user, per-project.

· In the Project Attributes Inspector for an application project, you can specify a help file and icons for both NT (**.ico**, **.ICO**) and Mach (**.eps**, **.tiff**).

· Project Builder by default sets tab stops at regular intervals of eight spaces each. There is now a defaults write, ªtabStopCharsº, that allows you alter this interval to any desired number of spaces, as long as that number is greater than zero.

4.1 Conversion Note

The **_main.m** files of 3.*x* applications have to be manually converted to the new **_main.m** content. To do this, copy the **main()** code from existing 4.1 projects or create a new project and copy its **main()** code. You can also copy and paste this code directly from here:

```
#import <AppKit/AppKit.h>

int main(int argc, const char *argv[]) {
return NSApplicationMain(argc, argv);
}
```

Known Issues in This Release < Windows

These issues are known to exist with this release on Windows:

Reference: 72980

Issue: Automatic **.def** file generation doesn't handle subprojects.

Description: The Project Builder feature that generates **.def** files only inspects the object (**.o**) files at the top level and overlooks the object files in subprojects. Complex projects<those with one or more subprojects<will therefore not build correctly. To work around this issue, add the following code to the **Makefile.postamble** of the library or framework.

```
ifeq "WINDOWS" "$(OS)"
$(WINDOWS_DEF_FILE): $(OFILES) $(OTHER_OFILES)
$(SILENT) if [ ! -r "./$(WINDOWS_DEF_FILE)" ] ; then \\
$(ECHO) -n "Generating $(notdir $@)...." ; \\
(cd $(OFILE_DIR); $(DUMP_SYMBOLS) $(OFILES) $(OTHER_OFILES) `$(CAT) $(NAME).ofileList` | $(EGREP)
"(SECT).*(External).*(\\|)" | $(EGREP) -v "(__GLOBAL_$I)|(_OBJC_)" | $(SED) "s/ _/ /" > $(TMPFILE)) ; \\
$(ECHO) "LIBRARY $(NAME).dll" > $(GENERATED_DEF_FILE) ; \\
$(ECHO) "EXPORTS" >> $(GENERATED_DEF_FILE) ; \\
$(CAT) $(TMPFILE) | $(EGREP) "(SECT2)|(.objc_c)" | $(AWK) '{printf "\\t%s CONSTANT\\n", $$NF}' >>
$(GENERATED_DEF_FILE) ; \\
$(CAT) $(TMPFILE) | $(EGREP) -v "(SECT2)|(.objc_c)" | $(AWK) '{printf "\\t%s\\n", $NF}' >>
$(GENERATED_DEF_FILE) ; \\
$(RM) $(TMPFILE) ; \\
$(ECHO) "done"; \\
fi
endif
```

Reference: 72815

Issue: Multiple Control-N's in rapid succession causes Project Builder to lock up

Description: Typing a series of Control-N characters one after the other causes Project Builder to display the Open Project panel. Clicking Cancel causes Project Builder to freeze. At this point, it can only be killed from Windows NT's Task Manager.

Reference: 72715

Issue: BooksOnline doesn't work when accessed from Project Builder on NT 3.51

Description: If you select BooksOnline from ProjectBuilder's Help menu on a system running Windows NT version 3.51, you'll discover that the links on the BooksOnline page appears to be broken. BooksOnline works correctly, however, if you invoke it from the OPENSTEP Enterprise program group.

Workaround: Access BooksOnline from the OPENSTEP Enterprise program group.

Reference: 72554

Issue: Source code versioning is error-prone with derived project files.

Description: Sometimes it might be difficult to keep derived project files (**Makefile** and *app***.iconheader**) and original project files (**PB.project**) synchronized in source-control situations. You can face a similar issue when you modify **Makefile** separately from **PB.project** and need to "back out" your changes.

Project Builder contains in its Resources directory a command-line tool that generates derived files from **PB.project**. The proper invocation of this tool, called FileWriter, is:

/NextDeveloper/Apps/ProjectBuilder.app/Resources/FileWriter -project [*path/*]PB.project -makefile [*path/*]Makefile [-iconheader *iconHeaderFile*]

Note that the **-iconheader** option is meaningful only on Mach.

Reference: 72542

Issue: LIBRARY_PATHS makefile variable not passed to linker

Description: If you add libraries to a project using Project Builder's Project->Add Files command, or if you add entries to the Library Search Order list in the project inspector, the LIBRARY_PATHS variable is created in the Makefile. However, this variable is not passed to the linker.

To work around this issue, assign the following value to the OTHER_LDFLAGS variable in **Makefile.preamble**:

OTHER_LDFLAGS = $(LIBRARY_PATHS)

Reference: 72344

Issue: Installation of **.lib** file in static library projects

Description: In static library projects (LIBRARY_STYLE=STATIC), the **.lib** file gets installed twice, once in the INSTALLDIR and once in the location specified by IMPORT_LIBRARY_DIR in **Makefile.preamble**. To have the **.lib** file installed only in the desired location (INSTALLDIR), set IMPORT_LIBRARY_DIR to INSTALLDIR.

Reference: 71975

Issue: The **libtool** utility does not recognize the **-read_only_relocs** flag.

Description: A serious side effect of this bug is that this option causes **libtool** to ignore all subsequent flags. Currently there is no workaround except for not using this flag.

Reference: 69061

Issue: Builds will fail if NEXT_ROOT has been modified to contain backward slashes.

Description: The installer specifies NEXT_ROOT with forward slashes, for example:

C:/NeXT/

Do not edit this variable in the Environment section of the System control panel, even if to change the forward slashes to backward slashes.

Reference: 72307

Issue: The Microsoft linker emits a bogus warning about CONSTANT keywords.

Description: When you build framework projects, you will see messages complaining about the use of CONSTANT keywords in your **.def** file. Because of issues with the linker, CONSTANT should be used in place of DATA. You can ignore the warnings.

Reference: 72308

Issue: Automatically generated **.def** files do not include public exported functions and variables.

Description: In creating the **.def** file for frameworks and dynamic libraries (DLLs), Project Builder handles Objective-C symbols and data but not functions or variables. If you have functions in your framework that need to be callable from the outside, or variables that should be externally accessible, define certain macros in a header file and then use them in your function declarations. These macros allow you to export non-static functions and variables from the DLL (*FRAMEWORK*_EXTERN) or to declare them as **extern**, but not exported (*FRAMEWORK*_PRIVATE_EXTERN).

Make a header file for each framework with functions and variables you wish to export (*Framework*Defines.h), and in it write the following macros (substitute your own

framework name for *FRAMEWORK*):

```
#ifndef _FRAMEWORKDEFINES_H
#define _FRAMEWORKDEFINES_H
#endif

#if defined(WIN32)

//
// For Windows
//

#ifndef _FRAMEWORK_BUILDING_DLL
#define _FRAMEWORK_WINDOWS_DLL __declspec(dllimport)
#else
#define _FRAMEWORK_WINDOWS_DLL __declspec(dllexport)
#endif

#ifdef __cplusplus
#define FRAMEWORK_EXTERN _FRAMEWORK_WINDOWS_DLL extern "C"
#define FRAMEWORK_PRIVATE_EXTERN extern "C"
#else
#define FRAMEWORK_EXTERN _FRAMEWORK_WINDOWS_DLL extern
#define FRAMEWORK_PRIVATE_EXTERN extern
#endif

#else

//
// For MACH and PDO
//

#ifdef __cplusplus
// This isnt extern "C" because the compiler will not
// allow this if it has seen an extern "Objective-C"
#define FRAMEWORK_EXTERN extern
#define FRAMEWORK_PRIVATE_EXTERN __private_extern__
#else
#define FRAMEWORK_EXTERN extern
#define FRAMEWORK_PRIVATE_EXTERN __private_extern__
#endif

#endif
```

You need to import this header in all your other headers and declare your function prototypes accordingly. Then, before building your framework, specify "-D_*FRAMEWORK*_BUILDING_DLL" in the Compiler Flags field of the Build Attributes inspector.

Additionally on Windows, Project Indexing doesn't work and, because of this, the ªDefinitionsº and ªReferencesº searches in the Project Find Panel don't work either.

Known Issues in This Release < Mach and Windows

Other issues with this release on both Mach and Windows are the following:

· When Escape is defined as the Meta key in Preferences (and Tab is bound to

indentation), Escape-/ (slash) does not cycle through all possible expansions (50288).

· Queries in the Project Find panel for macro references do not find existing uses of macros (55187).

· Comparing autosaved and last-saved versions of files in FileMerge does not work (56892).

· Header files in Framework projects do not become public by default (56924).

· Renaming a subproject doesn't rename the directory the subproject lives in (57211).

· You cannot switch to a second view when no files have been loaded into the code editor (57698). To workaround this issue, after selecting a text file in the upper browser, type Command-1 followed by Command-2. This switches back to a single view, and then splits it again so it can double the text file in the upper view.

· Indexing generates an error if a header file is empty (57790).

· Build errors in tear-off windows appear in the main editing view (58863).

· An exception may be raised when running a new executable (that is, after selecting a different executable from the Launcher Options panel) with no arguments selected when the previous executable had arguments. The workaround is to deselect the argments from the old executable before selecting the new one.

· Breakpoints on functions or methods without debugging information aren't displayed in the breakpoint inspector. (67785)

· Moving a breakpoint icon doesn't update the line number in the Breakpoint inspector. However, the location of the breakpoint is updated in **gdb**. (67712).

TextEdit

TextEdit is a new application based on the new text system. In addition to the standard text editing features in the 3.3 Edit application, it provides:

· "Wrap to Page" mode. This mode causes the document to be wrapped to the current page size (as opposed to the window size), and thus shows you a simple WYSIWYG representation of your pages. This mode also allows zooming.

· Support for new text object features such as kerning, ligatures, and baseline offsets.

· Ability to read/write plain text files in different 8-bit character encodings and Unicode. Coupled with the Kanji support in the new text object, you can read/write/edit Kanji files created by 3.3J or 4.1J. (You will need Kanji fonts and input manager.)

The alternate encoding to apply to a file is specified by a popup in the Open or Save panels.

The default item, "Default," tells TextEdit to use either the default 8-bit encoding of the system or Unicode. Other choices let you select different encodings. You can also set the default setting of this popup via the Preferences panel.

Sources to TextEdit are available with the developer software, in **/NextDeveloper/Examples/AppKit/TextEdit**.

Known Issues in This Release

Reference: 58895

Issue: Tabs in plain text mode

Description: Tabs in a plain text window are by default set to a multiple of the font width. However this setting isn't readjusted when the font is changed, so the tabs get out of sync.

Workaround: Either don't change the font of a plain text window on the fly, or change it via defaults and restart the application.

Reference: 58741

Issue: Displaying unrenderable characters too slow

Description: When given characters which are not valid for the current font, the text system might spend too much time trying to find a font to render them. This means that files with random binary data could take a long time to load.

Workaround: Avoid binary files. A few binary characters are probably fine, and will be displayed as boxes, but a total binary file (for instance, an executable), could keep TextEdit busy for a while.

Reference: None

Issue: Encoding popup in Open/Save panels not available under NT3.51

Description: Because accessory views aren't supported under NT3.51, there is no encoding popup in the Open/Save panels.

Workaround: You can use the popup in the Preferences panel to set the default choice for the popup, which will then be used when files are opened or saved.

In addition, please refer to the Application Kit release notes for the new text system bugs.

TrueType Fonts

This file contains release notes for the 4.1 TrueType font support. TrueType font support was introduced with the 4.0 release.

ttf2font

True Type font files can be converted to font files which are usable by the OpenStep Window Server and the Application Kit. The **ttf2font** command line utility converts a TrueType font file to a font directory which contains the Postscript Type 42 font definition as well as the Adobe Font Metrics file. The command line syntax is as follows

ttf2font [-o *outputPath*] *trueTypeFont.ttf*

where the **-o** option is used to identify the directory where **.font** files will be placed

As an example, the following command line converts the TrueType font file TIMES.TTF and places the resulting **.font** directory into the **~/Library/Fonts** directory using standard encoding:

ttf2font -o ~/Library/Fonts TIMES.TTF

Advanced options are also available and are as follows:

-v Verbose mode. All errors and messages are printed to standard output.

-e *encoding* Use a specific encoding scheme, where *encoding* is one of:

nextstep Nextstep encoding
standard Abobe standard encoding
isolatin1 ISO latin 1 encoding
symbol Symbol encoding
font Font-specific encoding

Encoding schemes stored within the font file are font-specific encoding schemes. The font vendor is responsible embeding a suitable encoding scheme for your platform.

Specifiying an encoding scheme other than **font**, causes the program to ignore the font specific encoding schemes stored within the file.

-p *platformID*
-s *platformSpecificID* Within a TrueType font file there are several tables which contain font specific encoding schemes. These encoding schemes are organized by platform; there can be more that one encoding scheme stored within a file, each identifying a different platform.

These options allow you to override the default platform. The *platformID* and *platformSpecificID* pair must identify a valid encoding scheme store within the file. The **-v** option allows you to observe the platform encoding schemes stored within the file. See *The TrueType Font Format Specification* for more details.

If no encoding option is specificed and the font does not contain alpha-numeric characters, the best font-specific encoding scheme is used. Otherwise, the default encoding is **standard**

encoding.

If no encoding schemes yield any glyph-to-character mappings, then all glyphs are linearly mapped to character codes 32 through 255.

Known Issues in This Release

· Printing of TrueType fonts can only performed on printers with Postscript interpreter versions greater that 2013 which have Type 42 font support.

· The TrueType fonts MS Line Draw and Symbol MT do not work.

Window Server

Notes Specific to Release 4.0

New Features in 4.0 (General)

A new release of DPS from Adobe (2015) has been integrated.

Better Font Support

This release includes support for CID fonts and TrueType (type 42) fonts. You can use the **ttf2font** conversion program to convert TTF files to a format suitable for use with OPENSTEP. (see TrueType release notes for details).

New Features in 4.0 (Mach Only)

Native 16-bit color support

We have implemented native support for RGB:555/16 framebuffers on Intel platforms . In previous releases, rendering to these framebuffers actually only used 4 bits per channel of precision (12 bits total). This new rendering implementation gives much improved color fidelity on RGB:555/16 displays. The only difference developers might notice is that **readimage** will now return 24 bit images from RGB:555/16 displays.

Backing Store Compression

The WindowServer now uses compression to conserve memory for window backing stores. Windows which have not been recently referenced are compressed. This leads to a slight increase in CPU usage by the WindowServer with the gain of significantly reducing memory requirements for window backing stores.

NXHosting

NXHosting is supported from 3.3 applications to the 4.0 WindowServer. NXHosting from 4.0 to 3.3 is not supported.

New Features in 4.0 (Window NT Only)

On Windows NT the WindowServer plays a different role in OPENSTEP than it does under Mach. It is not involved in Window region management or event distribution. Instead, it serves as a "drawing server" which interprets PostScript and provides backing stores for Windows windows. OPENSTEP applications still rendezvous with the WindowServer to do their drawing, but instead of creating windows via the WindowServer, they use WIN32 to create windows directly. The application then passes the Windows window number to the WindowServer and a backing store is created. All drawing is occurs in the WindowServer, and when **flushgraphics** is called, the backing store is transferred to the display via GDI's BitBlt.

NXHosting

NXHosting is not supported (inbound or outbound) on Windows NT.

Pixel Formats

We support drawing into the following DIB formats for backing stores:

8bit color (includes System Palette entries)
555 16bit color
565 16bit color
32 bit color

In Windows 16 color VGA mode, we use 8bit color backing stores. This mode is supported for diagnostics, but is not recommended and has some really bad color artifacts.

In Windows 32bit color mode, our rendering code currently does not gamma correct. This means that OPENSTEP applications will look dark, unless you display adaptor supports gamma correction in hardware.

EOF 2.0 NT ODBC Adaptor Patch

This patch is version number 13.3. The ODBC Adaptor shipped with the EOF 2.0 release was version 13.1. You can find the version of the ODBC adaptor in the title of the ODBC Login panel. This patch is **only** for use with EOF 2.0 installed on Windows NT as part of OPENSTEP or WebObjects.

The WebObjects Current Patch List, **TIL article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read these documents if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.

Installing the ODBC Adaptor Patch

Download the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/patches/2.0/ODBCAdaptorPatch_NT.tar.gz

In order to install this patch, you will need to use gzip and gnutar to expand the attachment. You'll end up with a supplemental NextLibrary directory, which you can then copy into your existing NextLibrary directory. You need to log in as Administrator to install this patch.

Caution: The patch will replace **\\NextLibrary\\Executables\\ODBCEOAdaptor.dll** and the entire **\\NextLibrary\\Frameworks\\ODBCEOAdaptor.framework** directory, so you should take care to create a back up these items before installing over the top of them.

Assuming you have **ODBCAdaptorPatch_NT.tar.gz** on c:/tmp and are using the Bourne Shell which ships with WebObjects or OPENSTEP Enterprise, here are the commands to install the patch:

```
$ cd $NEXT_ROOT
$ mv NextLibrary/Executables/ODBCEOAdaptor.dll NextLibrary/Executables/ODBCEOAdaptor.dll.bak
$ mv NextLibrary/Frameworks/ODBCEOAdaptor.framework NextLibrary/Frameworks/ODBCEOAdaptor.framework.bak
$ gzip -d -c c:/tmp/ODBCAdaptorPatch_NT.tar.gz | gnutar -xvf -
```

EOF ODBC Adaptor Patch Release Notes

Problems Fixed in This Patch Update

The following problems have been fixed in this update:

ODBC EOAdaptor

References: 73072

Problems: Attempts to save EO's that use the custom value capability will fail. an example is using the Movies example application and adding an image to a Talent. When you attempt to save the change, you will get an error: "NSImage does not respond to selector length".

Fix: The ODBCByteColumn and ODBCLongByteColumn classes now have a corrected implementation of takeInputValue: that calls adaptorValueByConvertingAttributeValue: to correctly convert the custom value into a NSString or NSData for storage purposes. See the EOF 2.0 release notes for the corrected implementation.

References: 73239

Problems: Attempts to reverse engineer a model from an existing ODBC datasource will fail with a dialog with the following message: "An unexpected error has occured which may cause EOModeler to malfunction. You may want to save copies of your open documents and quit EOModeler. Error: invalid name"

Fix: During model reverse engineering, the ODBC method desribeModelForTableNames is more careful to create valid names for it's EOEntities and EOAttributes. The previous adaptor just used the table name or column name and these names aren't always valid names for model objects. Additionally, while generating SQL we now add quotes around names of tables and columns if they contain any characters that aren't letters of the alphabet.

References: 74252

Problems: Creating an EOModel from a Microsoft Access database that uses replication will leave the s_GUID, s_Generation, and s_Lineage columns even though these aren't useful.

Fix: The reverse engineering code now looks for this column in Access databases, and will remove them from the list of classProperties and attributesUsedForLocking. If you want these columns included in your model, just mark them as class properties and/or attributes used for locking.

EOF 2.0 Release Notes

This file contains the most up-to-date release notes for release 2.0 of Enterprise Objects Framework.
This article has been archived and is no longer updated by Apple.
The MachOS version of this release is 3-way fat; it can be used to develop software for NeXT, Intel, and SPARC. The OpenStep for Windows version of this release can be used to develop software for Intel machines running Windows NT.

Notes Specific to Windows NT Developers

References to filenames in this document use UNIX format. On Windows NT, you can interpret these by reading backslashes for the slashes and adding the installation directory (**c:\\NeXT** by default) to the beginning. For example, **/NextLibrary/Documentation** on Windows NT is **c:\\NeXT\\NextLibrary\\Documentation**.

In order to use Enterprise Objects Framework on Windows NT, you must purchase appropriate client libraries from your database vendor.

Here's what you need:

Oracle

Phone: (800) 542-1170
Ask for SQLNET V2.2 for PC/Windows NT

The Oracle adaptor on NT requires the Oracle 7.2 Client Library. It won't work with the 7.1 libraries.

Sybase

Phone: (800) 685-8225
Ask for: Open Client Runtime for PC/Windows NT

Informix

Phone: (800) (800)331-1763
Ask for: ESQL/C for Win32

Converting Release 1.x Applications to 2.0 (Mach only)

Enterprise Objects Framework 2.0 for Mach includes **tops** scripts for performing source code conversion of your Enterprise Objects Framework 1.x applications to 2.0. Because of the magnitude of changes in the architecture of the 2.0 release, these scripts are by no means sufficient for automatically converting your application. However, once you've decided how the structure of your application will evolve to take advantage of the new architecture, these scripts can be useful in identifying and sometimes making specific API conversions. The scripts, along with instructions for running them, can be found in **/NextDeveloper/EOF1xTo2Conversion**.

For more information on the differences between Enterprise Objects Framework 1.x and Enterprise Objects Framework 2.0, see the document *Differences Between Enterprise Objects Framework 1x and 2.0.* You can find it on-line in **/NextLibrary/Documentation/EnterpriseObjects/1x_To_2**.

Installing the Examples

This release provides on-line examples to help familiarize you with Enterprise Objects Framework 2.0. These examples are located in **/NextDeveloper/Examples/EnterpriseObjects**. Installing the examples involves these steps:

· Setting up users and databases on your database server for the example databases.
· Installing the example directory.
· Populating your database server with example data.

Setting up Database Accounts

The Enterprise Objects Framework 2.0 examples use two sets of tables: Movies and Rentals. Some examples use just one of the these databases, while others use both. The multi-database support in Enterprise Objects Framework 2.0 makes it possible for you to install these databases in three different configurations:

· Both sets of tables together in a single user/database.
· Each set of tables in its own user/database on the same database server.
· Each set of tables on its own database server (for example, Movies on Informix, Rentals on Oracle).

Depending on your desired setup, you use the tools available with your database server to set up one or two new user/databases. For example. on Sybase you might create a new database on your server called ªMoviesº and login with the user ªsaº. On Oracle you might create a new user with the name ªMoviesº. Once you have set up these accounts, you're ready to install the examples.

Copying the Example Directory

To configure and build the examples you need to copy the example directory to a writable area in your file system. You can do this by copying the **/NextDeveloper/Examples/EnterpriseObjects** folder into your home directory (or any other directory writable by you).

Configuring the Example Models

The model files used by the examples must be configured to use your adaptor and server. To configure the examples, run the **configure_examples** program in your copy of the examples directory. It will ask you for the name of the adaptor you wish to use (Informix, Oracle, Sybase, and so on) and for the login information for your database. It will then convert the example models for your server.

Populating the Databases

Now that the examples are configured, you can fill your example databases with sample data. The **install_database** tool in the **DatabaseSetUp** directory will connect to your databases, add the example tables, and fill them with data. If you later wish to remove the data, simple run the **drop_database** tool.

Building the Example Programs

With your example projects installed and your database filled with data, you are ready to build and run the examples. To do this, in a command shell **cd** to your example directory and type **make all**. This performs a **make install** on **BusinessLogic.framework** and **EOExtensions.framework** to put them in **/LocalDeveloper/Frameworks**, where they are shared by many of the other examples. It then makes all of the examples applications.

Note: The **/LocalDeveloper/Frameworks** directory must be created and writable by you in order to build the examples. On Mach this can be accomplished by using **su** to become the superuser and then executing the following commands:

```
mkdirs /LocalDeveloper/Frameworks
chmod a+w /LocalDeveloper/Frameworks
```

Enterprise Objects Framework Defaults

This section lists the user defaults for which Enterprise Objects Framework checks and changes its behavior.

Defaults in the NSGlobalDomain

To change these defaults, issue a command such as the following from a shell:

defaults write NSGlobalDomain EOAdaptorUseBindVariables NO

EOFDebugEditingContext
Default is NO.
EOControl Layer will log every time an object is changed.

EOFDebugUndo

Default is NO.
Logs each time something is pushed on or popped off an undo list.
Also logs in [_EOUndoStack dealloc]

EOAdaptorDebugEnabled
Default is NO.
Logs for connection attempst, all transaction activity (begin, rollback, commit), and SQL statements (SELECT, UPDATE, etc.).

EOProjectSourceSearchPath
An optional array of paths in which EOAccess will search for framework project directories that contain models.

EOAdaptorUseBindVariables
Default is YES.
Controls whether or not the SQL generation process will use bind variables (for Oracle and Informix).

EOOracleTableNamesSQL
SQL statement (default is "SELECT TABLE_NAME FROM USER_TABLES ORDER BY TABLE_NAME")
If you would like the model re-engineering process to look at a subset of the tables in the given schema, you can provide your own SQL statement like "SELECT TABLE_NAME FROM USER_TABLES ORDER BY TABLE_NAME where table_name not in ('MY_USELESS', 'FOO')".

EOOracleUseNoWaitLocks
Default is NO.
Controls whether Oracle uses NOWAIT locks.

EOSybaseInterfacesFile
Default is unset.
If this default is set, the SybaseAdaptor will initialize the client library to run with this interface file. This default is not applicable on Windows NT.

EOSybaseTableNamesSQL
This default can be used to change the default SQL used to determine the tables that will be analyzed in creating a new model.
Default is "select name from sysobjects where type = 'U' or type = 'V'".

EOSybaseAttributeSQL
SQL statement used to get the attribute information for a given table.
Default is "select a.name attr_name, b.type attr_type, b.name type_name, b.allownulls allownulls, c.type primary_key, a.length width, a.prec prec, a.scale scale from syscolumns a, systypes b, syskeys c where a.id = object_id('%@') and a.id *= c.id and (a.colid *= c.key1 or a.colid *= c.key2 or a.colid *= c.key3 or a.colid *= c.key4) and (c.type = 1 or c.type is null) and a.usertype = b.usertype and datalength(a.name) > 0 order by a.name".

EOSybaseRelationshipSQL
Default is "select a.keycnt, b.name tname, c.name cname, d.name dtname, e.name dcname from syskeys a, sysobjects b, syscolumns c, sysobjects d, syscolumns e where (b.type = 'U' or b.type = 'V') and a.depid is not null and a.depid > 0 and b.id = a.id and b.id = c.id and ((c.colid = a.key1 and e.colid = a.depkey1) or (c.colid = a.key2 and e.colid = a.depkey2) or (c.colid = a.key3 and e.colid = a.depkey3) or (c.colid = a.key4 and e.colid = a.depkey4)) and d.id = a.depid and d.id = e.id order by b.name, d.name".

EOSybaseStoreProcedureSQL
Default is "select name, id from sysobjects where type = 'P'".

EOSybaseStoredProcedureDetailsSQL
Default is "sp_sproc_columns %@".

InformixINFORMIXSERVER
No default value.
The name of the Informix server.

InformixInformixTableNamesSQL
This default can be used to change the default SQL used to determine the tables that will be analyzed in creating a new model.
Default is "select tabname, owner, tabid from informix.systables where (tabid > 99) and (tabname <> 'ANSI') order by tabname".

Defaults in the EOModeler Domain

To change these defaults, issue a command such as the following from a shell:

defaults write EOModeler DisableInheritenceCheck YES

BundlesToLoad
If you write extensions to EOModeler, you can get EOModeler to load them by setting this default. This default is an array, so remember to include parentheses when you set it. For example:

defaults write EOModeler BundlesToLoad "(/NextDeveloper/Apps/EOModeler.app/Resources/DiagramEditor.bundle, $HOME/eoexamples/ModelerBundle/ModelerBundle.bundle) "

RECORD_FETCH_LIMIT
Default is 100.
For the Data Browser in EOModeler. This controls how many rows to fetch before asking users if they want to fetch all, fetch another n rows, or just stop now.

Consistency Checks
All of these have the default NO.
DisableConsistencyCheckOnSave
DisableExternalNameCheck
DisableInheritenceCheck
DisablePrimaryKeyCheck
DisableRelationshipCheck
DisableStoredProcedureCheck

SkipBeautifyNamesOnModelCreation
Default is NO.
Setting this default to YES will cause EOModeler to leave the entity names and attribute names matching the exact names of their corresponding database objects (including the case).

DisableAdvancedOptions
Default is NO.
If set to YES, the EOModler runs in "Simplified mode". The advanced inspectors don't appear, the choices of table view columns is limited, and so on.

New Features for 2.0

· A new class, EOEditingContext, that manages an object graph and coordinates change notification. This class is also responsible for change tracking and undo. One EOEditingContext can also be nested inside another, thereby supporting nested in-memory transactions.

· Support for multiple databases.

· NSDecimalNumber, a class that provides a lossless representation of decimal numbers.

· User interface formatting and validation.

· Updatable relationships: Your business logic may now update relationship pointers in the object graph and the framework will automatically generate the appropriate foreign keys changes to affect the change in the database.

· Referential integrity rules. You can explicitly add referential integrity rules in EOModeler. They will be enforced by Enterprise Objects Framework in your running application.

· Improved support for modeling inheritance.

· Enterprise object±based validation.

· Update support for flattened attributes.

· Schema creation. You can use the Generate SQL command in EOModeler to generate SQL for a selected entity or entities.

· Automatic primary key generation: The Framework can now automatically assign primary keys for newly inserted objects.

· Structured qualifiers<that is, qualifiers are now independent of database and SQL.

· Incremental model loading for improved performance. Models now consist of an **.eomodeld** directory in which each entity has its own file. Entity descriptions are loaded into your application only as needed.

· Support for Informix servers.

· An ODBC adaptor (Windows NT only).

· Improved support for Oracle stored procedures.

· Reverse engineering of primary keys and relationships on all supported databases (Informix, Oracle, and Sybase). Enterprise Objects Framework can now read this information from the database and incorporate it into a model.

· The Sybase adaptor is now based on CT-Lib.

· The ability to edit the UserInfo dictionary in EOModeler.

For more discussion of these features, see the document *Differences Between Enterprise Objects Framework 1x and 2.0.*

New Features Shared with Enterprise Objects Framework 1.2

· An Informix adaptor is included in this release.

· Adaptors are now frameworks. Just as with the old bundle-based adaptors, framework adaptors can be dynamically or statically linked. If you need to reference a class defined in a particular adaptor from your application code (for example, the InformixChannel class), you have to add the adaptor to the Frameworks list for your project.

If you have custom adaptors that you're converting to 2.0, you need to convert them into frameworks. If you do this, note that you may encounter issues linking to the client libraries that weren't present when you were loading your adaptor as a bundle. For example, you can't use common symbols. If you use undefined symbols, you need to set a flag in the linker to tell it to ignore those symbols.

· EOAdaptor's use of **adaptor.info** has been removed. Instead, the **Info-*platform*.plist file** from the adaptor's bundle is consulted for the adaptor class name and adaptor major version number. The key names are as follows:

EOAdaptorMajorVersion
EOAdaptorClassName

To add key-value pairs to the infoDictionary, add an ASCII property list file named **CustomInfo.plist** to the supporting files category of your project. The project makefiles will automatically merge this into the **Info.plist** that is derived from your project.

· The following Enterprise Objects Framework 1.1 classes have been renamed and moved into the AppKit: NXTableView (renamed to NSTableView), and NXImageView (renamed to NSImageView).

· EOApplication is obsolete. NSApplication now manages the autorelease pool.

Login Panel Loading Changes

The Enterprise Objects Framework version 1.2 and 2.0 handle login panels differently than version 1.1 in order to factor them into separate bundles, thereby eliminating any link dependency on the AppKit in both the adaptors themselves and in EOAccess. This change allows a single adaptor binary to be used in both OpenStep for Windows and D'OLE. To convert your Enterprise Objects Framework 1.1 adaptor to the new API you must:

· Create a new bundle subproject called "LoginPanel" in your adaptor project, and move the login panel source files and nib file there.

· Remove the AppKit from the list of frameworks for the main bundle and add it (along with EOAccess and Foundation) to the **LoginPanel.bproj**.

· Change your LoginPanel class to subclass from EOLoginPanel rather than NSPanel.

· Change your login panel nib file so that the login window is a subclass of NSPanel (not your EOLoginPanel subclass). Change your file's owner to be the EOLoginPanel subclass.

· Implement - (NSDictionary *)runPanelForAdaptor:(EOAdaptor *)adaptor validate:(BOOL)validate
See **/NextDeveloper/Examples/EnterpriseObjects/FlatFileAdaptor/LoginPanel.bproj/ FlatFileLoginPanel.m** for an example implementation).

New Methods and Behavior

For a description of how Enterprise Objects Framework 2.0 differs from the preceding releases, see the document *Differences Between Enterprise Objects Framework 1x and 2.0.* See **/NextLibrary/Documentation/EnterpriseObjects/1x_To_2**.

Locating the Documentation for this Release

The documentation for this release is provided in RTF (readable on Mach only) and in PDF format to be readable (and printable) on all platforms. On Windows NT, documentation is available in the ªOpenStep Books Onlineº item of the OPENSTEP Enterprise program group. You can also find the documentation in the following on-line locations:

· The *Differences Between Enterprise Objects Framework 1x and 2.0* document describes how the product has changed between the 1x and 2.0 releases. See **/NextLibrary/Documentation/EnterpriseObjects/1x_To_2**.

· The *Enterprise Objects Framework Developer's Guide* provides a conceptual overview of the product. In addition to the hard copy book, a pre-production version of the book is provided on-line in PDF format. See **/NextLibrary/Documentation/NextDev/EnterpriseObjects/Guide**.

· The *Enterprise Objects Framework Reference* includes class specifications for the Enterprise Objects Framework classes. Reference documentation is located in **/NextLibrary/Frameworks** in one of these locations:

Known Issues in Release 2.0

Enterprise Objects Framework

These issues exist in this release of Enterprise Objects Framework:

Reference: 73506

Issue: Adding categories to the concrete adaptor classes (such as SybaseAdaptor) breaks the login panel on NT.

Description: If you add a category to a concrete adaptor class, whenever your application encounters an invalid connection dictionary the login panel won't appear.

Workaround: If you add a category to a concrete adaptor class, subsequently invoking **bundleForClass:** returns the bundle in which your category lives. Unfortunately,
Enterprise Objects Framework uses this method to load the LoginPanel bundle. To work around this issue you need to copy the **LoginPanel.bundle** from the adaptor resources directory (such as **SybaseEOAdaptor.framework/Resources**) into the resources directory of the application or framework to which you added the category.

Reference: 73506

Issue: EOActionAssociation doesn't present an error when it's given a bad selector.

Description: If the user types the wrong selector for the action key, the action association simply does nothing when the button is pressed. It should instead raise an exception or log so that developers have a better chance of detecting the typo.

Workaround: When a button wired with an EOActionAssociation doesn't trigger the expected behavior in an application, double-check that the key exactly matches the selector name.

Reference: 73448

Issue: When you send an EOEditingContext an **insertObject:** message immediately followed by a **deleteObject:** message, the EOEditingContext does not forget the object.

Description: Deleting newly inserted objects from an EOEditingContext does not remove them from the registered objects list. This is an issue because they can then be edited (for example, a relationship they are set on can be reset, causing the reverse, outbound relationship to be updated). Editing these objects puts them in the updated objects list, but they don't have a global ID, so the EOEditingContext raises an exception when it is sent **saveChanges** (this is good, because the deleted objects shouldn't be in the updated list in the first place).

Workaround: Send the EOEditingContext a **processRecentChanges** message before invoking **deleteObject:**.

Reference: 73414

Issue: The EODisplayGroup delegate method **displayGroupDidChangeSelection:** isn't invoked if a different object is selected under the same selection indexes.

Description: The EODisplayGroup delegate method, **displayGroupDidChangeSelection:** is invoked only when the list of selected *indexes* changes, not when the list of selected *objects* changes. So if the selection is at index 0 and a new object is inserted at index 0 and selected, the delegate is not called. This can be an issue in an inheritance application like Inventory, which displays a different sub-panel depending on the class of the selected object. When inserting a new object, the selection index may stay the same but a different object (the new one) is selected. If the new object is of a different class than the old, an exception will likely result when the old (inappropriate) sub panel refreshes.

Workaround: The delegate can register as an observer of the EODisplayGroup so that it gets **subjectChanged** messages when the contents have changed. It can then check that the **selectedObjects** array has changed, and if so forward itself the **displayGroupDidChangeSelection:** message.

Reference: 73219

Issue: Setting a delegate on an EOEditingContext that doesn't implement the method **editingContext:shouldPresentException:** causes exceptions to not be presented.

Description: If an EOEditingContext is assigned a delegate but that delegate doesn't implement **editingContext:shouldPresentException:**, then the EOEditingContext acts as if the method was implemented to return NO. This is incorrect; it should have the same behavior as when the delegate is not set: exceptions should be presented (via the message handler).

Workaround: When setting an EOEditingContext delegate, always implement **editingContext:shouldPresentException:** to return YES.

Reference: 72933

Issue: When the user framework adds a category to Enterprise Objects Framework classes, Enterprise Objects Framework fails to find **License.table** file.

Description: Enterprise Objects Framework verifies that certain features are licensed by looking up a **License.table** file in the the Resources directory of the EOAccess bundle. If a user application includes a framework that adds categories on certain Enterprise Objects Framework classes, Enterprise Objects Framework will incorrectly look for the license file in the user framework rather than EOAccess, resulting in Enterprise Objects Framework considering the feature as unlicensed

Workaround: Copy the **License.table** file from **/NextLibrary/Frameworks/EOAccess.framework/Resources** into the resources of the framework project that adds the category to Enterprise Objects Framework. *** Note that it is in violation of your software license agreement to use this technique to enable features of Enterprise Objects Framework for which you are not legally licensed.

Reference: 72903

Issue: Undo/Redo doesn't record unsuccessful deletions correctly

Description: When the deletion of an object fails due to a deny rule, the undo manager records an empty undo group. This means that although nothing actually happened during the operation, the operation will need to be undone before previous operations can be undone. For interactive programs this is not normally an issue since users rely on visual cues to determine how many times to undo. However, this may be an issue for code that programmatically performs undo operations.

Workaround: None.

Reference: 72795

Issue: The "New Editor..." menu item is missing on NT .

Description: The "New Editor" menu item is not present in the NT nib file. "New Editor" allows you to have two different windows open on the same document. This is helpful when you need to compare two entities.

Workaround: Since the implementation exists in EOModeler, you can actually just edit EOModeler's main nib on NT and get this working:

1. Go to $(NEXT_ROOT)/NextDeveloper/Apps/EOModeler.app/Resources/English.lproj
2. Make a backup copy of EOModelerNT.nib. In a shell type:
cp -r EOModelerNT.nib EOModelerNT.nib.original
3. Use Interface Builder to open the nib.
4. Use the "Classes" folder tab to add the **newEditor:** action to the EOModeler class.
5. Add a "New Editor" menu item in the "Tools" menu. Put it just above the "Preferences..." item.
6. Create the target/action connection from this new menu item to the **newEditor:** action in "File's Owner".

Reference: 72714

Issue: In-memory descending sort on a property than contains **nil**s does not work correctly.

Description: When you use EOSortOrdering to perform a descending in-memory sort of an array of objects in which the sorted property may contain **nil**, objects containing **nil** are sorted inconsistently.

Workaround: Add the following category to your application:

```
@implementation NSObject (_FIXEOSortOrderingComparison)
- (NSComparisonResult)compareDescending:(id)other
{
NSComparisonResult result;

if (other == [EONull null]) return NSOrderedAscending;
result = [(NSString *)self compare:other];
return (result == NSOrderedSame) ? result : -result;
}
@end
```

Reference: 72619

Issue: EOAdaptorChannel does not inherit EOAdaptor's delegate.

Description: According to the EOAdaptorChannel class specification and header file, the EOAdaptorChannel's delegate should automatically be kept in synch with its adaptor. However, if an EOAdaptor has been created and assigned a delegate, newly-created EOAdaptorContexts and EOAdaptorChannels are not automatically assigned the delegate. However, if a new delegate is assigned to an EOAdaptor, it's propagated to any of that adaptor's existing contexts and channels.

Workaround: Wait until all of the channels and contexts are instantiated before assigning the adaptor's delegate, or reassign the adaptor's delegate each time a new channel or context is created.

Reference: 72603

Issue: Column appears twice in SQL insert statement.

Description: This happens whenever a sub-entity has a flattened to-one relationship that is also in the parent entity. In this case, the column of the source attribute of the relationship appears twice in the insert statement.

Workaround: Ensure that the source attribute in the flattened to-one relationship in the sub-entity is *not* marked as a primary key, usedForLocking, or as a class property. This workaround has the adverse effect that the attribute will not be used for locking purposes.

Reference: 72531

Issue: EOEditingContext leaks object record structs when forgetting objects.

Description: Whenever an object is forgotten (unregistered) from an EOEditingContext (for example, when releasing the EOEditingContext), an internal structure is leaked.

Workaround: This bug is patched in WebObjects 3.0. OpenStep applications can plug this leak by executing the following statements during application initialization:

```
[EOEditingContext _enableFreeingObjectRecords:YES];
[EOUndoManager _setFreesUndoStacks:YES];
```

Reference: 72527

Issue: Foreign keys are not inserted into database as expected.

Description: In the case where an entity contains an attribute that is not marked as usedForLocking, as a class property, or as a primary key, and the attribute isn't used in any relationship on that entity, then the attribute won't be included in the SQL insert statement.

Workaround: Mark the attribute as used for locking.

Reference: 72483

Issue: To-many relationship properties in newly inserted objects aren't being properly initialized.

Description: Newly inserted objects should automatically get empty arrays assigned to their to-many relationship properties, so that when these properties are subsequently sent an **addObject:** message, everything works correctly.

Workaround: In the **awakeFromInsertionInEditingContext:** method of your enterprise object class, initialize variables that represent to-many relationships with new NSMutableArrays.

Reference: 72269

Issue: You can't tell Enterprise Objects Framework to not undo your changes when delete propagation fails.

Description: The EOEditingContext delegate method **editingContextShouldUndoUserActionsAfterFailure:** is supposed to allow programs to indicate that they do not want user actions undone if a validation or delete propagation error occurs. However, the EOEditingContext undoes the user action regardless of the return value from the method.

Workaround: None.

Reference: 72177

Issue: Deleted objects are still registered in the EOEditingContext after a **saveChanges** operation.

Description: If an object is deleted in the EOEditingContext and then the EOEditingContext is saved, the deleted object isn't forgotten by the EOEditingContext (i.e., sending the EOEditingContext the message **objectForGlobalID:** should return **nil**, but it doesn't).

Workaround: Fortunately, this should have no affect on most applications. However, if you need to work around this issue, remember the deleted objects in the **editingContextWillSaveChanges:** delegate, and then invoke **forgetObject:** for each object after a successful save.

Reference: 72027

Issue: PDO: EOKeyValueCoding is broken for doubles on HPUX

Description: EOKeyValueCoding is not working correctly for accessor methods that set and return doubles on HPUX under PDO 4.1 (and previous releases). This means that users cannot correctly fetch enterprise objects that have class properties with accessor methods that use doubles.

Workaround: Change your enterprise objects to use NSNumber *, NSDecimalNumber *, or **int** accessors.

Reference: 71553

Issue: EOPickTextAssociation displays an alert panel whenever the '[' character is entered.

Description: EOPickTextAssociation should either escape all substitution characters or wait until a complete expression is typed in before executing. Since it does not, EOQualifier thinks that it has found an illegal pattern and raises an exception, which the EOPickTextAssociation displays in an alert panel.

Workaround: None.

Reference: 70937

Issue: Validation methods don't check relationship optionality.

Description: Relationships can be marked as optional or mandatory in the Relationship Inspector of EOModeler. The validation methods supplied by Enterprise Objects Framework should verify that all relationships that are marked as mandatory have at least one object in them, but this property is ignored.

Workaround: Implement the check in your own validation method.

Reference: 70847

Issue: After disconnecting all EOColumnAssociations from a table view, you can't connect to a different EODisplayGroup.

Description: If the columns are connected via EOColumnAssociations to one EODisplayGroup, disconnected, and then you

attempt to connect a column to a different EODisplayGroup, all of the EODisplayGroup's properties appear as gray in the Inspector-- a connection is not allowed.

Workaround: This is actually a feature! When the first EOColumnAssociation was created, an EOTableViewAssociation was bound to the table itself. This association remains connected to the original EODisplayGroup even after the column has been disconnected, and this connection prevents columns from being connected to a different EODisplayGroup. To make the new connection, click on the table view and disconnect the EOTableAssociation.

Reference: 70260

Issue: Some validation error messages returned by the Framework have not been localized.

Description: Some validation error messages returned by the Framework's default validation methods (such as methods that check that a value doesn't exceed the maximum width specified in its attribute) are not localized.

Workaround: Implement an error handler for use with the EOEditingContext and have that handler look for the localized string in a file that the programmer has created.

Reference: 70049

Issue: EOModelGroup doesn't raise an exception when more than one entity has the same name.

Description: Although it is illegal to have the same entity name in two different models in a model group, EOModelGroup doesn't check to see if this is the case when adding a model.

Workaround: Verify that no two models have the same entity name in them either manually or by writing a method to perform the check.

Reference: 69934

Issue: EOQualifier needs a case insensitive 'like' operator.

Description: EOQualifier needs a case insensitive 'like' operator that works both in memory and in SQL.

Workaround: You can use a pattern like '*[Hh][Ee][Ll][Ll][Oo]*' or you can create a method on the enterprise object that always returns a version in uppercase and use that method as a key in the qualifier.

Reference: 69678

Issue: Enterprise Objects Framework does not insert or delete rows in the database in a way that is compatible with the database's referential integrity constraints.

Description: Enterprise Objects Framework performs its database operations in an order that causes the database's referential integrity constraints to be violated.

Workaround: Implement the **databaseContext:willOrderAdaptorOperationsFromDatabaseOperations:** method on the EODatabaseContext and order the adaptor operations so that they are compatible with the database's referential integrity constraints. For more discussion of this subject, see the section "How Do I Order Database Operations?" in the chapter "Answers to Common Design Questions" in the *Enterprise Objects Framework Developer's Guide*.

Reference: 69670

Issue: When you use the 'like' operator in a format string that's specified as an argument to the EOQualifier method **qualifierWithQualifierFormat:**, the operator is only recognized when it is all lowercase

Description: This method raises an exception when given a format string such as: "name LIKE 'fred'" because it only recognizes the LIKE operator when it is in lower case letters.

Workaround: Use 'like' instead of 'LIKE'.

Reference: 69039

Issue: Alert panel displaying adaptor error is never dismissed.

Description: This occurs whenever an adaptor operation that was invoked from an **awakeFromNib:** method displays an alert panel. The issue is that the entire object graph is not yet instantiated when **awakeFromNib:** is invoked.

Workaround: Database operations should be begun from the **applicationDidFinishLaunching:** method rather than the **awakeFromNib:** method. Of course, this means that any methods that indirectly cause database communication should also be invoked from the **applicationDidFinishLaunching:** method.

Reference: 46679

Issue: All private instance variables should be **@private** or begin with _.

Description: All instance variables in Enterprise Objects Framework should be considered private.

Workaround: Don't access Enterprise Objects Framework instance variables in client programs.

Reference: 46967

Issue: Using delete propagation triggers in database can cause Enterprise Objects Framework to become out of sync.

Description: The use of delete propagation triggers in the database instead of the model may cause Enterprise Objects Framework to become out of sync. This becomes a bigger issue if the Framework is executing several operations as part of a transaction and the transaction is rolled back by a trigger rule.

Workaround: See the chapter ªAnswers to Common Design Questions,º in the *Enterprise Objects Framework Developer's Guide* for information on handling this issue.

Reference: 47202

Issue: Conversion from money to double doesn't always work.

Description: Database number types are sometimes more precise than a C **float** or **double**. Consequently when these numbers are read in from the database, stored in a double, and then written back out to the database, rounding errors may appear. For instance, the value `2078927178.0000' is converted as `2078927178.0000002384185791'.

Workaround: Use the NSDecimalNumber class for money.

Reference: 47832

Issue: Don't mark as ªused for lockingº those attributes in the model with a custom data type unless the custom value class implements a value-based **isEqual:** method.

Workaround: Implement **isEqual:** on the custom data type and don't mark it used for locking.

Reference: 51250

Issue: You can't join on derived attributes.

Description: Invalid SQL is generated whenever an derived attribute is designated as a join attribute in a relationship.

Workaround: None.

Reference: 52557

Issue: Enterprise Objects Framework wrongly generates **t0.*nil***.

Description: Enterprise Objects Framework sometimes inappropriately generates SELECT statements that include text like ªt0.*nil*º. For example, this can happen when you make a column with no column name, a column with a column name like ªconvert(varchar(12), 'Default')º, or derived attributes with no column name.

Workaround: None.

Reference: 53598

Issue: Enterprise Objects Framework doesn't support to-one relationships joining on candidate (partial primary) keys in the destination.

Description: Enterprise Objects Framework doesn't support to-one relationships that join on only part of a compound primary key of the destination entity. This is because the Framework bases its uniquing of fetched objects on their full primary keys. If Enterprise Objects Framework fetches an object with a to-one relationship, it must look that object up in the uniquing table to see if it is already in memory. If it isn't, Enterprise Objects Framework must create a fault for it. Because objects are uniqued by their full primary keys, a candidate key is insufficient to do the lookup. Even doing lookups by both full primary key and by candidate key doesn't work, because a fault created for one relationship joined on the full primary key can't be correlated with a fault for another relationship joined to the same row based on the candidate key.

Workaround: Use a to-many relationship and define accessor methods for the enterprise object that emulate the to-one relationship by getting and setting the first object of the relationship array.

Reference: 61475

Issue: When performing a inheritance fetch, we need to group the fetches by tables.

Description: Enterprise Objects Framework does not currently take advantage of the union table method of inheritance mapping to perform a deep fetch of an inheritance hierarchy via a single fetch of all columns. Intead, it currently executes multiple fetches against the same table.

Workaround: The entire hierarchy can be mapped as a single entity and then EOModelGroup delegate methods can be used to tell Enterprise Objects Framework how to allocate the proper subclasses.

Reference: 64084

Issue: Inserted enterprise objects don't get removed from EODisplayGroup after sending **revert** to EOEditingContext.

Description: If you fetch objects into an EODisplayGroup and then insert a few objects and delete a few objects, and update a few objects, telling the EOEditingContext to revert will back out the updates, but not insertions or deletions.

Workaround: The actual insertions and deletions have been reverted, but the EODisplayGroup doesn't know how to revert its object list (since is doesn't keep track of what its original object list was before the insertion or deletions). The easiest workaround is to programatically tell all affected EODisplayGroups to refetch after telling the EOEditingContext to revert.

Reference: 64283

Issue: Enterprise Objects Framework 2.0 examples merge with obsolete Enterprise Objects Framework 1.1 examples.

Description: If a system has Enterprise Objects Framework 1.1 Developer installed on it (EODeveloper.pkg) and then upgrades to 4.0, the EODeveloper package (incorrectly) stays installed, and the examples stay in **/NextDeveloper/Examples/EnterpriseObjects**.

When the user later installs EO2Developer, the Enterprise Objects Framework 2.0 examples are merged with the Enterprise Objects Framework 1.1 example files already in **/NextDeveloper/Examples/EnterpriseObjects**.

Workaround: Uninstall 1.1 EODeveloper.pkg before installing EO2Developer.pkg.

Reference: 64968

Issue: Seemingly innocuous qualified fetch always causes exception.

Description: Some qualified fetches raise exceptions because values in the SQL have been formatted as strings when they should have been formatted as some other type.

This can happen whenever an external type has been entered erroneously that does not actually map to a column type recognized by the database. It may also occur when a Sybase model has no record of user defined types that have been used in the model.

Workaround: In the case of an erroneous external type definition, simply correct it. In the case of a user defined type, create a new model by reverse engineering the database, and copy the connection dictionary with the user defined type information from the new model to the original one.

Reference: 65165

Issue: **install_database** doesn't work: Sybase: Can't find type `decimal'.

Description: The **install_database** script in the **EnterpriseObjects/DatabaseSetUp** directory doesn't work for Sybase 4.9 servers.

When the models in the examples directory were converted to Sybase, the server version wasn't taken into account. Some of the attributes were converted to ªdecimalº data type and the Sybase 4.x server doesn't know about these.

Workaround: Use EOModeler to find and change all the external types from decimal to float in each of the models in your examples directory.

Reference: 68146

Issue: Fault failure leaves EOInterfaceLayer unstable.

Description: If an entity being displayed has a to-one relationship and the row with the corresponding foreign key cannot be found in the database, when you try to access the source object your user interface gets into a corrupted state.

Workaround: Enterprise Objects Framework raises an exception when a to-one relationship cannot be resolved (because of a referential integrity issue in the database). If this exception is raised by user interface code (for example, in displaying a master-detail relationship) the state of the user interface control objects can get corrupted. To prevent this you must prevent the exception. One way is to trap the exception by implementing the EODatabaseContext delegate method **databaseContext:failedToFetchObject:globalID:**. The other is to use a to-many relationship in your model instead of a to-one.

Reference: 68604

Issue: Repeated false alert that Enterprise Objects Framework 1x nib file is being converted to Enterprise Objects Framework 2.0.

Description: When you reopen a nib file after conversion you get the message: ªThis Enterprise Objects Framework 1x nib file has been translated to Enterprise Objects Framework 2.0. If you did not intend to convert to Enterprise Objects Framework 2.0, unload EOPalette, quit Interface Builder without saving this file, and reopen the nib.º

Workaround: Quit Interface Builder, then reopen the nib file.

Reference: 69211

Issue: Link errors on Windows NT.

Description: Programs on Windows NT must add explicit references to at least one class in each framework in order to avoid link errors at run time.

Workaround: Add a function like that in the following code snippet, which refers to classes in each of Enterprise Objects Framework's layers. Though never invoked, it forces the appropriate linking to occur.

```
#ifdef WIN32
#import <EOControl/EOControl.h>
#import <EOAccess/EOAccess.h>
#import <EOInterface/EOInterface.h>

void _referenceAllEOFrameworks()
{
[EODisplayGroup new]; // EOInterface
[EOEntity new]; // EOAccess
```

```
[EOEditingContext new]; // EOControl
}
#endif
```

If you create your project with the type "EOF Application," this code is automatically added to your project main file.

Oracle Adaptor

These issues exist in the Oracle adaptor supplied with this release of Enterprise Objects Framework:

Reference: 73333

Issue: The Oracle adaptor has character set issues on Sparc and m68k.

Description: The Oracle adaptor on Mach does not properly support certain character set conversion on certain architectures:

· On SPARC ISOLatin1 works, but Japanese character sets do not.
· On m68k non-ASCII ISOLatin1 characters are stripped and Japanese character sets don't work at all.

On Intel all character sets work fine, including European and Japanese.

Workaround: No workaround for this issue on EOF 2.0 is currently avaialable.

Reference: 62425

Issue: Oracle Adaptor doesn't read stored procedures inside of packages.

Description: There is no way to get the database to tell you the components (procedures and functions) that are inside a package definition. Clients can still create stored procedures in the model that will call into packages, it's just that model description using EOModeler won't create these at connect time.

Workaround: You can use EOModeler to create the stored procedure definitions in the model. Just set the external name of the stored procedure to *package-name***.***procedure-name*.

Reference: 63348

Issue: Converted models have no width information<Oracle fetches empty strings.

Description: The Enterprise Objects Framework 2.0 Oracle Adaptor has issues if you attempt to use an eomodel file from the Enterprise Objects Framework 1.0 release. These model files don't contain width information for string values, which results in all the strings being fetched with 0 length. If this happens for the column that is the primary key, you will also have issues with uniquing since every row will appear to have the same key.

Workaround: Use EOModeler to add width information for VARCHAR2 and RAW columns.

Sybase Adaptor

These issues exist in the Sybase adaptor supplied with this release of Enterprise Objects Framework:

Reference: 74943

Issue: Unable to correctly reverse-engineer schemas whose tables have more than 4 primary key components.

Workaround: Use the following defaults command executed in a shell-- note the use of key5 - key 8; the reason it stops at 8 is that Sybase limits the number of keys to 8:

```
defaults write NSGlobalDomain EOSybaseAttributeSQL '"select a.name attr_name, b.type attr_type, b.name type_name, b.allownulls allownulls, c.type primary_key, a.length width, a.prec prec, a.scale scale from syscolumns a, systypes b, syskeys c where a.id = object_id('\\"%@'\\") and a.id *= c.colid and (a.colid *= c.key1 or a.colid *= c.key2 or a.colid *= c.key3 or a.colid *= c.key4 or a.colid *= c.key5 or a.colid *= c.key6 or a.colid *= c.key7 or a.colid *= c.key8) and (c.type = 1 or c.type is null) and a.usertype = b.usertype and datalength(a.name) > 0 order by
```

a.name"

Reference: 74633

Issue: Can't link against the Sybase1x framework.

Description: The Sybase1x framework has a bug in its sybase1x.lib, such that anything linked against it will incorrectly attempt to load the nonexistent Sybase.dll (rather than Sybase1x.dll). If you just write code to the EOAdaptor generic level, things will work fine, but if you reference anything like SybaseChannel or SybaseColumn you won't be able to initialize your application (or framework).

Workaround: Make a copy of the Sybase1x.dll named Sybase.dll.

Reference: 73321

Issue: You can't update a BLOB and non-BLOB value in the same row.

Description: If you attempt to update a BLOB attribute and a non-BLOB attribute in the same row, the update to the non-BLOB attribute will succeed, but the update to the BLOB will fail because the adaptor attempts to get the io_desc structure with a SELECT statement that includes a WHERE clause for the old (pre-update) non-BLOB value. Thus, the adaptor doesn't get the io_desc, and the transaction rolls back.

Here is the SQL from an example in which the attributes "name", "image1", and "image2" have been changed:

Sep 27 14:21:43 trey[3138] *** executing SQL: UPDATE TREY_TEST SET NAME = 'test', IMAGE2 = 0xFFFF, IMAGE1 = 0xFFFF WHERE (PK = 24 AND NAME = 'foo')]
Sep 27 14:21:43 trey[3138] *** [executing SQL: SELECT t0.IMAGE1 FROM TREY_TEST t0 WHERE (t0.PK = 24 AND **t0.NAME = 'foo'**)]

Clearly, the name should no longer be 'foo' since it was just updated it to 'test'.

Workaround: Change the database schema to put the BLOB's into their own table accompanied only by a primary key that the adaptor doesn't update.

Reference: 73136

Issue: If an entity has more than 1 BLOB, updating one of the values will cause the other(s) to be set to 0xFFFF.

Description: When the Sybase adaptor is updating a row in which a BLOB value has changed, it first sets the value of the BLOB to 0xFFFF, and then it SELECT's the row in order to get the io_desc structure so it can write the BLOB. Unfortunately, the code that replaces the updated BLOB values with 0xFFFF is also replacing the BLOB values that didn't change with 0xFFFF.

Workaround: In order to work around this issue, you need to implement one of the delegate methods that gets called during the generation of SQL for updating the rows.

Reference: 72641

Issue: The Sybase DLL is not found when you run Enterprise Objects Framework 2.0 applications on Windows.

Description: The Sybase DLL is not furnished with the Enterprise Objects Framework 2.0 installation packages.

Workaround: The Sybase DLL and the necessary associated files are available through **TIL aricle 724712**. You must download and install these files.

Reference: 61481

Issue: When debugging, the new Sybase CT-Lib adaptor blocks if you you try to step over a call that requires a trip to the Sybase server.

Description: GDB hangs when you use the **next** command to step over a line of code which eventually causes a call to the Sybase client library.

Workaround: Set a breakpoint after the line and use **continue** rather than **next**.

Reference: 61999

Issue: An update fails for text that disallows NULL and has an empty field.

Description: Whenever a text or image column is being updated, the Sybase adaptor attempts to ensure that the column has been initialized correctly by assigning NULL to it. In cases where null is not allowed this does not work.

Workaround: Modify the table definition to allow nulls.

Reference: 62634

Issue: The Sybase adaptor is using **CS_CONVERT()** to convert numeric data into NSDecimalNumber.

Description: Fetching decimal numbers in locales that use a characters other than `.' for the decimal may not work.

Workaround: None.

Informix Adaptor

These issues exist in the Informix adaptor supplied with this release of Enterprise Objects Framework:

Reference: 74201

Issue: The Informix adaptor doesn't support the Japanese version of Informix.

Description: The Informix adaptor is based on a version of the Informix client library that doesn't include internationalization support.

Workaround: None.

Reference: 70232

Issue: Informix adaptor raises an exception when you try to sort on attributes that are not in the select list.

Description: Due to a restriction in the Informix adaptor, it's not possible to sort on attributes that aren't included in the select list. This means that it isn't possible to sort the results using an attribute that is not marked on the entity as either a primary key, used for locking, or a class property.

Workaround: If possible, add the attribute to the entity and mark it as used for locking. Otherwise, there is no workaround.

Reference: 63225

Issue: Informix adaptor does nothing for **returnValuesForLastStoredProcedureInvocation**.

Description: The Informix adaptor will not return variable values for stored procedures.

Workaround: Don't use stored procedures. If you need to access their logic, use an intermediate table to hold return values and then SELECT them back to your client.

Reference: 64031

Issue: UserDefaults are different between Enterprise Objects Framework1.2 and Enterprise Objects Framework2.0 InformixAdaptors.

Description: In Enterprise Objects Framework 1.2, the InformixAdaptor stores defaults in the following domain EOFInformixAdaptor and uses the following keys:
INFORMIXDIR, DBDATE, DBLANG, DBMONEY, InformixLogErrors, ShowSystables, ShowTableOwner, Beautify, DefaultIsolationLevel, GlobalOptimization, GlobalExplain, GlobalLockMode, GlobalPDQPriority, GlobalDataSkip, GlobalConstraints, DatabaseExclusive

Enterprise Objects Framework 2.0 stores defaults in the standard NSGlobalDomain and prefixed all keys with ªInformixº, that is:
InformixINFORMIXDIR, InformixDBDATE, InformixDBLANG, InformixDBMONEY, InformixLogErrors, InformixShowSystables, InformixShowTableOwner, InformixBeautify,, InformixDefaultIsolationLevel, InformixGlobalOptimization, InformixGlobalExplain, InformixGlobalLockMode, InformixGlobalPDQPriority, InformixGlobalDataSkip, InformixGlobalConstraints, InformixDatabaseExclusive.

Workaround: None.

ODBC Adaptor

These issues exist in the ODBC adaptor supplied with this release of Enterprise Objects Framework:

Reference: 73072

Issue: ODBC cannot save custom classes

Description: When you try to save a custom class (such as NSImage), an exception is raised with the message "NSImage does not respond to selector length raise." ODBC does not appear to be converting these classes to NSData like the other adaptors.

Workaround: A fixed version of the ODBC adaptor is available as **TIL article 72477**.

For anyone who is implementing an adaptor based on the ODBC example, here is the corrected source:

```
@implementation ODBCByteColumn
...
- (void)takeInputValue:(id)value
{
// Check for nulls
if(value == [EONull null]) {
_returnedLength = SQL_NULL_DATA;
return;
} else {
id primValue;
const void *bytes;
int length;
primValue = [_attribute adaptorValueByConvertingAttributeValue:value];
if ([primValue isKindOfClass:[NSString class]])
primValue = [primValue dataUsingEncoding:_encoding allowLossyConversion:YES];

if (![primValue isKindOfClass:[NSData class]])
[NSException raise:EOGeneralAdaptorException format:@"unable to create a byte representation for class \\"%@\\"", [primValue class]];

bytes = [primValue bytes];
length = [primValue length];
memcpy(_value, bytes, length);
_returnedLength = length;
}
}

@end

@implementation ODBCLongByteColumn
...
- (void)takeInputValue:(id)value
{
// Check for nulls
if(value == [EONull null]) {
_returnedLength = SQL_NULL_DATA;
return;
} else {
id primValue;
```

```
const void *bytes;
int length;
primValue = [_attribute adaptorValueByConvertingAttributeValue:value];
if ([primValue isKindOfClass:[NSString class]])
primValue = [primValue dataUsingEncoding:_encoding allowLossyConversion:YES];

if (![primValue isKindOfClass:[NSData class]])
[NSException raise:EOGeneralAdaptorException format:@"unable to create a byte representation for class \\"%@\\"", [primValue class]];

bytes = [primValue bytes];
length = [primValue length];

if (_valueLength < length) {
[self freeValue];
_valueLength = length;
[self allocateValue];
}
memcpy(_value, bytes, length);
_returnedLength = length;
}
}

@end
```

Issue: The ODBC adaptor source code provided as an example is only available on OpenStep for Windows NT.

Description: The source code for the ODBC adaptor is available on Windows NT as an example. It is not, however, included on Mach or PDO.

Workaround: Copy the source code from an NT machine or use the FlatFile adaptor (included on all releases) instead.

Reference: 70193

Issue: The ODBC adaptor does not support the stored procedure API.

Workaround: Subclass the adaptor and implement the functionality.

EOModeler

These issues exist in EOModeler with this release of Enterprise Objects Framework:

Reference: 73684

Issue: When you convert a model from 1.x to 2.0, any relationship information in the user dictionary is lost.

Workaround: Before opening the 1.x model in EOModeler 2.0, open a copy of it in Edit and perform a Find and Replace to convert "userDictionary" to "userInfo". Open the modified copy of the model in EOModeler.

Reference: 73585

Issue: In EOModeler on Windows NT, the "Preferences..." menu item is always disabled.

Workaround: One solution is to use Interface Builder to open the EOModeler NT nib file and make a target connection from the "Preferences..." menu item to File's Owner **preferences:** action.

Alternatively, you can use use the defaults database to control everthing in the Preferences panel, by issuing a command such as the following in a shell:

default write EOModeler DisableStoredProcedureCheck YES

You can use this technique to change all of the settings (listed below) that are normally modified through the Preferences

panel. Note that the default setting for all of these items is NO.

RecordFetchLimit (number) Limits the number of rows fetch before
the Data Browser asks you if you want to
fetch more.
DisableAdvancedOptions (BOOL) Run EOModeler in simplified mode
DisableConsistencyCheckOnSave(BOOL) Don't check consistency before saving
DisablePrimaryKeyCheck(BOOL) Don't check for primary keys
DisableRelationshipCheck(BOOL) Don't check relationship definitions
before saving
DisableExternalNameCheck(BOOL) Don't check for external names before
saving
DisableInheritenceCheck(BOOL) Don't check for inheritance issues
DisableStoredProcedureCheck(BOOL) Don't check for valid stored procedure usage

Reference: 73064

Issue: Putting an invalid name in the Parent column raises an exception.

Description: In the table mode view of entities in EOModeler, if you use the "Parent" field to enter the name of an entity that doesn't exist, you will get an uncaught exception with a message such as "NSInlineString does not respond to selector reason".

Workaround: Don't set the name to an an entity that doesn't exist. After this happens, save your changes and exit EOModeler.

Reference: 72926

Issue: Dragging an EOEntity into a newly-added nib doesn't always work if you already have the EOModel in the project

Description: Dragging an EOEntity into a nib will fail if the nib was recently added to the project. The general sequence of events leading to this issue is as follows:

1. Open an existing project that already includes an EOModel.
2. Open an existing nib.
3. Create a new nib, and save it into the project.
4. Try to drag an entity out of the model into your nib.

Now Interface Builder will ask you if you want add the model to your project, even thought the model is already in the project. Regardless of your answer, you won't see the EODisplayGroup or EOEditingContext show up in your new nib.

The issue is that each nib file gets assigned a model group when it is first opened, so the new nib starts with an empty model group. The bug is that the model group isn't being updated when you save the nib into a project.

Workaround: Revert the document.

Reference: 72662

Issue: If your model has compound primary keys and uses inheritance, performing a consistency check will raise an exception.

Description: If you have a model with compound primary keys and you're using inheritance, running a consistency check will raise an exception, even if the model is fine. This is tied to the inheritance checking performed by a consistency check.

Workaround: You can disable inheritance checking. This is useful if you have compound primary keys and no inheritance. To do this, use the following command from a shell:

defaults write EOModeler DisableInheritenceCheck YES

Reference: 67804

Issue: EOModeler can't find model from another framework.

Description: Issue 1: When you load a nib file into your application, it can't find the model you have in your framework. Issue 2: When you save changes to a model file in your framework, the change isn't reflected in open nib files.

Enterprise Objects Framework 2.0 finds models for an application by looking for all models in the application and in any frameworks used by the application. By default Enterprise Objects Framework looks for referenced framework in their *installation* location. Thus if you don't have the framework that contains the model installed, Enterprise Objects Framework won't find the model. Similarly, a change saved to a model in the framework project isn't noticed by Interface Builder since it's looking at the *installed* version, not the source version.

Workaround: You can tell Enterprise Objects Framework to look at the source for your framework projects by using the following defaults command (executed in a shell):

defaults write NSGlobalDomain EOProjectSourceSearchPath "($(HOME)/myProjectsDirectory1, /myOtherProjectsDirectory)"

Then, when Interface Builder or EOModeler is looking for models contained in one of your frameworks, it will first search all project directories within **$(HOME)/myProjectsDirectory1** and **/myOtherProjectsDirectory** before searching for the built versions.

Reference: 64339

Issue: Derived attributes don't work properly.

Description: Sometimes when you're trying to create a derived attribute, you may encounter seemingly random errors<the pop-up list in the Inspector reverting to Column, the text you typed in the field being erased or reverted, error panel telling you ªUnable to modify the attribute,º and so on.

Workaround: Always add a definition immediately after changing the attribute to from Column to Derived. Once you add a definition for a derived attribute, it can't be deleted<you can change it, but a definition must be present.

Reference: 62444

Issue: When you change a text field in an EOModeler Inspector and don't press Return, you can lose your changes.

Workaround: Always use the Return key.

Reference: 62447

Issue: Last column in EOModeler table mode isn't handled correctly when you resize.

Description: The last column in a table view can get clipped. If you widen the second-to-last column by dragging its right edge, the last column becomes narrower and the scroll knob doesn't appear until the mouse approaches the edge of the table view. If you save a model with a clipped column, then when you open it again the column remains clipped even if the browser is big enough to handle it.

Workaround: Widen the last column by dragging its right-most edge before widening the second-to-last column.

Reference: 62669

Issue: In EOModeler, the external types field isn't case insensitive for word-completion

Description: In the External Types field of the Attribute table view, word-completion needs to be be case-insensitive. For example, typing `v' should complete to `VARCHAR' just like typing `V' does.

Workaround: None.

Reference: 62727

Issue: Editing in Inspector with editing still active in table doesn't work.

Description: If you edit something in table mode, then, without tabbing out of the edited column, make a change in the Inspector, the change made in the table column is lost.

Workaround: None.

Reference: 63118

Issue: Schema generation may produce identifiers that are too long.

Description: If you have database table names that are long, the names generated for constraints may be too long.

Workaround: Keep your table names shorter, or edit the SQL EOModeler generates to keep the constraint names shorter.

Reference: 63119

Issue: EOModeler generates bogus foreign key constraints for compound keys.

Description: Schema generation in EOModeler can produce some confused constraint definitions for Oracle and Informix if you have non-normalized data (such as the TALENT and TALENT_PHOTO tables).

Workaround: You can work around this by editing the SQL generation scripts, or by just not asking EOModeler to generate the constraint information.

Reference: 63169

Issue: Models created from version 4.9 Sybase servers do not include stored procedures.

Workaround: Use EOModeler's Stored Procedure Editor to add the EOStoredProcedure objects to the model.

Reference: 63183

Issue: Trying to generate schema SQL will raise if any of the primary key attributes don't have a column name.

Workaround: None.

Reference: 69386

Issue: Trying to drag a model or an entity from EOModeler into a nib file sometimes fails.

Description: If you try to drag a model or an entity from EOModeler into a nib file, Interface Builder asks if you would like to add this model to the project. Sometimes the attempt to add the model to the project will fail.

Workaround: Relaunch Interface Builder by double-clicking on the nib icon in Project Builder. Try dragging the EOModel or EOEntity now<everything should work.

Reference: 59472

Issue: Derived attributes are limited and don't offer full SQL as advertised

Description: Placing a string or a numeric constant in the definition field of a derived attribute will cause invalid SQL to be generated. Definitions such as ªtitleº and ª0.0º will not work correctly. However, definitions such as ªatt1 + 5º should work correctly when ªatt1º specifies another attribute.

Workaround: None.

Reference: 57842

Issue: EODisplayGroups are missing their keys.

Description: Enterprise Objects Framework was probably unable to find the model file containing the entity used by the EODisplayGroup. To verify this, inspect the data source of the EODisplayGroup (click on the EODisplayGroup, bring up the Inspector panel, and selected the DataSource panel from the Inspector popup). If the ªModelº field is blank, then Enterprise Objects Framework was unable to find your model.

Workaround: Quit Interface Builder and verify that the model containing the entity referenced in the EODisplayGroup is

added as a resource in the project containing the nib file.

On-line Examples

Reference: 73332

Issue: The Studios example has a bad hard-coded path in its framework search order that keeps it from building on NT.

Description: If you try to build the Studios example on NT, the build will fail due to a bad path in framework search path.

Workaround: To correct this issue, follow these steps:

1. Open the project in Project Builder.
2. Choose Tools -> Inspector.
3. In the Inspector's Build Attributes view, use the second pop-up menu to display Framework Search Order.
4. Remove **d:\\NeXT\\NextLibrary\\Frameworks** from the search path list.

Reference: 73076

Issue: Oracle stored procedures example doesn't work

Description: The external names of the stored procedures are missing the prefix 'MOVIE_PROCEDURES.' This causes them to not work.

Workaround: Use the Stored Procedure view in EOModeler to change the external names of the two fetch procedures to MOVIE_PROCEDURES.FETCH_MOVIE_WITH_PRIMARY_KEY and MOVIE_PROCEDURES.FETCH_MOVIES_ALL.

Reference: 70557

Issue: The Customer example fails to propagate change to credit card.

Description: The relationship between CreditCard and Member is not modeled correctly in the examples. In the Customer application, you can modify a the number and type of a member's credit card, but the change to the primary key is not propagated to all of the objects that it relates to. Consequently, after saving the changes to the database, the credit card's number and type will have changed but the foreign key in the member table will still have the old values as the foreign key. This relationship would work correctly had the CreditCard class been modeled with an primary key identifier that was distinct from its number and type values and if the relationship were constructed on that primary key attribute. This would also be a more efficient implementation.

Workaround: None.

Reference: 69199

Issue: Error running **configure_examples** script on Windows NT.

Description: Running **configure_examples** will fail unless your path is properly specified.

Workaround: In order to install and run examples on NT, you need to add the following to your system path (in the System Control Panel):

.;c:\\NeXT\\LocalDeveloper\\Executables

(The above assumes that $NEXT_ROOT is defined as **c:\\NeXT**).

Reference: 69419

Issue: Example data for Movie and Rental models must be installed in different databases

Description: When installing data for more than one model in a database, the **eo_sequence_table** is only properly initialized for the first model installed.

Workaround: You can either install the data for each model in a different database or change the last line in the **install_database** script located in the DatabaseSetUp directory of your examples directory as follows:

Change this:

${EOUTIL} dump ../BusinessLogic/Rentals.eomodeld -source plist database -schemaCreate -postInstall < RentalData.plist

To this:

${EOUTIL} dump ../BusinessLogic/Rentals.eomodeld -source plist database -schemaCreate -postInstall -force < RentalData.plist

When you use the **-force** option as a workaround, exceptions are logged because the **eo_sequence_table** table and **eo_pk_for_table** procedure already exist when you execute **install_databases**. You can just ignore these exceptions.

Reference: 68231

Issue: **make all** in the Enterprise Objects Framework examples fails sometimes.

Description: The Enterprise Objects Framework examples will fail to make if **${NEXT_ROOT}/LocalDeveloper** is present on your system and you don't have write access to it. The makefile tries to install the BusinessLogic framework in the **/LocalDeveloper/Frameworks** directory.

Workaround: Execute **make** as root or ask your system administrator to create a **/LocalDeveloper/Frameworks** directory and make it writable by you.

Creating Custom Project Types for ProjectBuilder

ProjectBuilder uses a set of built-in Project Types such as Application and Framework to describe standard types of projects that have proven useful in quickly developing typical applications of OPENSTEP. While most all development efforts can use combinations of projects instantiated from these project types (and organized hierarchically in a tree structure), it is possible to extend these project types. At launch time, PB reads the following search path, loading in project type definitions:

$NEXT_ROOT/NextLibrary/PrivateFrameworks/DevKit.framework/Resources/$LANGUAGE.lproj/ProjectTypes
$NEXT_ROOT/NextDeveloper/ProjectTypes
$NEXT_ROOT/LocalDeveloper/ProjectTypes
$HOME/Library/ProjectTypes

By loading the site-specific and user-specific project type definitions later, the built-in types can not only be augmented, but overridden. All you need do is place a new .projectType wrapper on this search path and re-launch ProjectBuilder.

This document assumes that you are using OPENSTEP release 4.1.
This article has been archived and is no longer updated by Apple.
To create a new project type definition called MyApplication, create a MyApplication.projectType directory with the following two components:

A "projectTemplate" directory containing the initial contents of projects that are created from this projectType. For example, a standard Info Panel and set of local frameworks could be added to the Application project template so that a new app could be site-specific "right out of the box".

An "Info.table" textual property-list file describing attributes of the Project Type. Valid keys include:

Allowable_SubprojectTypes - A list of names of subprojects which are valid as subprojects of this type of project.

AttributesInspector - The name of the Objective-C class that implements the "Project Attributes" Inspector in PB. Built into PB are: SubprojectInspector, ApplicationInspector, FrameworkInspector, LegacyInspector, PaletteInspector

DefaultExtension - The name a project gets by default (e.g. .bproj, .woa).

GeneratedFiles - The list of files this project derives and maintains itself (e.g. Makefile, iconHeader).

MAKEFILE - The name of the makefile that should be used to build this project (e.g. aggregate.make).

MAKEFILEDIR - The directory containing **MAKEFILE** (e.g. "$(NEXT_ROOT)/NextDeveloper/Makefiles/project")

Other_Keys - List of other keys (briefcases) in project. These and the other keys below are simply conceptual groupings of briefcases. ProjectBuilder will always display the briefcases grouped in a particular order. Otherwise, all briefcases are basically equal.

Resource_Keys - List of resource keys (briefcases) in project.

Source_Keys - List of source keys (briefcases) in project

Subproj_Keys - List of subproject keys (briefcases) in project.

Targets - The set of build targets these projects support by default in MAKEFILE.

PBProjectTypeSubClass - The name of the Objective-C class in PB that implements the customization functionality for this project type. Built into PB are: **PBApplicationProjectType**, **PBToolProjectType**, **PBPaletteProjectType**

ProvidesIcons - If set to "Yes", hints to PB that icons should be emmited for inclusion in the built binary file.

Public_Keys - The list of keys (briefcases) in which the "Public" attribute can be set.

DisplayName - The actual name that should be used in the PopUpList in PB when creating a new project. If not present, the base name of the .projectType wrapper

AliasNames - Other names this project type was previously known as (e.g. Subproject).

KeyForType - The Makefile key in the parent project this project is recorded under.

Localizable_Keys = The list of keys (briefcases) in which the "Localizable" attribute can be set.

CanCreateInExistingDirectory - If set to"Yes", this project can be created inside an existing directory. Otherwise, PB requires that it create a new directory from scratch for the project.

You can use /NextDeveloper/ProjectTypes/EOF Application.projectType as an example.

NSNumberFormatter

Inherits From: NSFormatter : NSObject

Conforms To: NSObject (NSObject)
NSCoding
NSCopying
Declared In: Foundation/NSNumberFormatter.h

Class Description

Instances of NSNumberFormatter format the textual representation of cells that contain NSDecimalNumbers and convert textual representations of numeric values into NSDecimalNumbers. The representation encompasses integers, floats, and doubles; floats and doubles can be formatted to a specified decimal position. NSNumberFormatters can also impose ranges on the numeric values that cells can accept.

NSControl provides delegation methods that permit you to validate cell contents and to handle errors in formatting. See the specification of the NSFormatter class for details.

When a cell with a NSNumberFormatter is copied, the new cell retains the NSNumberFormatter object instead of copying it. You remove an NSNumberFormatter from a cell by specifying **nil** as the argument of NSCell's **setFormatter:** method.

Instances of NSNumberFormatter are mutable.

Creating an Instance of NSNumberFormatter

The easiest way to use NSNumberFormatter is to drag a formatter onto a control in Interface Builder. However, if you're not using Interface Builder to create your user interface or if you simply want more fine-grained control over an NSNumberFormatter (for example, to change the text attributes of the values displayed), you can create and manipulate instances of the class programmatically.

To create an NSNumberFormatter, allocate an instance of NSNumberFormatter and use one or more of NSNumberFormatter's ªset formatº methods to set its format. You then use NSCell's **setFormatter:** method to associate the NSNumberFormatter

instance with a cell.

For example, the following code excerpt creates an instance of NSNumberFormatter, sets its formatting for positive, zero, and negative values, and applies it to the cell of an NSTextField using NSCell's **setFormatter:** method:

```
NSNumberFormatter *numberFormatter =
[[[NSNumberFormatter alloc] init] autorelease];
[numberFormatter setFormat:@"$#,###.00;0.00;($#,##0.00)"];
[[textField cell] setFormatter:numberFormatter];
```

The value of a cell (NSCell) is represented by an object, typically an NSDecimalNumber object in this case. When this value needs to be displayed or edited, the cell passes its object to the NSNumberFormatter instance, which returns the formatted string. When the user enters a string, or when a string is programmatically written in a cell (using **setStringValue:**), the cell obtains the equivalent NSDecimalNumber object from the NSNumberFormatter.

The most common technique for assigning a format to an NSNumberFormatter object is to use the method **setFormat:**, as shown above. This method takes as an argument an NSString whose contents can be one of the following:

· @º*positiveFormat*º
  For example, @º$###,##0.00º (the syntax of format strings is discussed in the following section).
· @º*positiveFormat;negativeFormat*º
  For example, @º###,##0.00;(###,##0.00)º.
· @º*positiveFormat;zeroFormat;negativeFormat*º
  For example, @º$###,###.00;0.00;($###,##0.00)º. Note that zero formats are treated as string constants.

As implied in the preceding list, you're only required to specify a format for positive values. If you don't specify a format for negative and zero values, a default format based on the positive value format is used. For example, if your positive value format is ª#,##0.00º, an input value of ª0º will be displayed as ª0.00º.

If you don't specify a format for negative values, the format specified for positive values is used, preceded by a minus sign (-).

If you specify a separate format for negative values, its separators should be parallel to those specified in the positive format string. In NSNumberFormatter, separators are either enabled or disabled for all formats<both your negative and positive formats should therefore use the same approach.

As an alternative to using the **setFormat:** method, you can use the **setPositiveFormat:** and **setNegativeFormat:** methods.

Format String Syntax

Format strings can include the following types of characters:

· Numbers

Format strings can include numeric characters. Wherever you include a number in a format string, the number is displayed unless an input character in the same relative position ªoverwritesº it. For example, suppose you have the positive format string @ª9,990.00º, and the value 53.88 is entered into a cell to which the format has been applied. The cell would display the value as 9,953.88.

· Separators

Format strings can include the period character (.) as a decimal separator, and comma character (,) as a thousand separator. If you want to use different characters as separators, you can set them using the **setDecimalSeparator:** and **setThousandSeparator:** methods. When you enable localization for an NSNumberFormatter object by using the method **setLocalizesFormat:**, separators are converted to characters appropriate to the environment in which the application is running.

· Placeholders

You use the pound sign character (#) to represent numeric characters that will be input by the user. For example, suppose you have the positive format @º$#,##0.00º. If the characters 76329 were entered into a cell to which the format has been applied, they would be displayed as $76,329.00. Strictly speaking, however, you don't need to use placeholders. The format strings @º,0.00º, @º#,#0.00, and @º#,##0.00º are functionally equivalent. In other words, including separator characters in a format string signals NSNumberFormatter to use the separators, regardless of whether you use (or where you put) placeholders. The placeholder character's chief virtue lies in its ability to make format strings more human-readable, which is especially useful if you're displaying formats in the user interface.

· Spaces

To include a space in a format string, use the underscore character (_). This character inserts a space if no numeric character has been input to occupy that position.

· Currency

The dollar sign character ($) is normally treated just like any other character that doesn't play a special role in NSNumberFormatter. However, when you enable localization for an NSNumberFormatter object by using the method **setLocalizesFormat:**, the dollar sign character is converted to the currency symbol appropriate for the environment in which the application is running.

All other characters specified in a format string are displayed as typed. The following table shows examples of the how the value 1019.55 is displayed for different positive formats:

Format String Display

@ª#,##0.00º 1,019.55

@ª$#,##0.00º $1,019.55

@ª___,__0.00º 1,019.55

Working with Values as Attributed Strings

In NSNumberFormatter, positive, negative, zero, **nil**, and ªnot a numberº values are NSAttributedStrings. NSAttributedString objects manage character strings and associated sets of attributes (for example, font and kerning) that apply to individual characters or ranges of characters in the string. An association of characters and their attributes is called an *attributed string*. For more information on NSAttributedString, see the NSAttributedString class cluster specification in the *Foundation Kit Reference*, and the NSAttributedString Class Cluster Additions specification in the *Application Kit Reference*.

Because the values displayed by NSNumberFormatter are attributed strings, you can customize aspects of their appearance, such as their color and font. The NSNumberFormatter methods you use to do this are as follows:

- -·textAttributesForPositiveValues
- -·setTextAttributesForPositiveValues:
- -·textAttributesForNegativeValues
- -·setTextAttributesForNegativeValues:
- -·attributedStringForZero
- -·setAttributedStringForZero:
- -·attributedStringForNil
- -·setAttributedStringForNil:
- -·attributedStringForNotANumber
- -·setAttributedStringForNotANumber:

Using Separators

NSNumberFormatter supports two different kinds of separators: thousand and decimal. By default these separators are represented by the comma (,) and period (.) characters respectively, and by default they're disabled.

All of the following statements have the effect of enabling thousand separators:

```
// use setFormat:
[numberFormatter setFormat:@"#,###"];

// use setHasThousandSeparators:
[numberFormatter setHasThousandSeparators:YES];

// use setThousandSeparator:
[numberFormatter setThousandSeparator:@"_"];
```

If you use the statement [numberFormatter setHasThousandSeparators:NO], it disables thousand separators, even if you've set them through another means.

Both of the following statements have the effect of enabling decimal separators:

```
// use setFormat:
[numberFormatter setFormat:@"0.00"];

// use setDecimalSeparator:
[numberFormatter setDecimalSeparator:@"-"];
```

When you enable or disable separators, it affects both positive and negative formats. Consequently, both formats must use the same separator scheme.

You can use the **thousandSeparator** and **decimalSeparator** methods to return an

NSString containing the character the receiver uses to represent each separator. However, this shouldn't be taken as an indication of whether separators are enabled<even when separators are disabled, an NSNumberFormatter still knows the characters it uses to represent separators.

Separators must be single characters. If you specify multiple characters in the arguments to **setThousandSeparator:** and **setDecimalSeparator:**, only the first character is used.

You can't use the same character to represent thousand and decimal separators.

NSCell Methods for Number Formatting

NSCell provides methods that give you almost the same behavior as instances of NSNumberFormatter. Send **setEntryType:** to a cell to associate it with an NSNumberFormatter object; specify the numeric format with one of the constants listed below. The constant is equivalent to an NSNumberFormatter initialized with a certain range and a conversion specifier:

Constant Range Specifier

NSIntType MININT, MAXINT %d
NSPositiveIntType 1, MAXINT %d
NSFloatType -MAXFLOAT, MAXFLOAT %g
NSPositiveFloatType MINFLOAT, MAXFLOAT %g
NSDoubleType -MAXDOUBLE, MAXDOUBLE %g
NSPositiveDoubleType MINDOUBLE, MAXDOUBLE %g

Send NSCell's **isEntryAcceptable:** to a cell to determine if it can accept a numeric type as indicated by one of the above constants. Send NSCell's **setFloatingPointFormat:left:right:** to specify the number of digits that appear to the left and right of the decimal point. By invoking this method you do not lose any range of values for floats or values set either through **setEntryType:** or by initializing an NSNumberFormatter directly.

Note: The NSNumberFormatter approach is recommended over the NSCell methods because it allows you greater freedom in specifying the representation of numbers. However, NSCell's **setEntryType:**, **isEntryAcceptable:**, and **setFloatingPointFormat:left:right:** are OpenStep-compliant, whereas NSNumberFormatter is an extension to OpenStep.

Instance Methods

allowsFloats

-·(BOOL)**allowsFloats**

Returns YES if the receiver allows as input floating point values (that is, values that include the period character (.)), NO otherwise. When this is set to NO, only integer values can be provided as input. The default is YES.

See also: -·setAllowsFloats:

attributedStringForNil

-·(NSAttributedString *)**attributedStringForNil**

Returns the NSAttributedString used to display **nil** values. By default **nil** values are displayed as an empty string.

See also: -·**attributedStringForNil**

attributedStringForNotANumber

-·(NSAttributedString *)**attributedStringForNotANumber**

Returns the NSAttributedString used to display ªnot a numberº values. By default ªnot a numberº values are displayed as the string ªNaNº.

See also: -·**attributedStringForNotANumber**

attributedStringForZero

-·(NSAttributedString *)**attributedStringForZero**

Returns the NSAttributedString used to display zero values. By default zero values are displayed according to the format specified for positive values; for more discussion of this subject see the section ªCreating an Instance of NSNumberFormatterº in the Class Description.

See also: -·**setAttributedStringForZero:**

decimalSeparator

-·(NSString *)**decimalSeparator**

Returns an NSString containing the character the receiver uses to represent decimal separators. By default this is the period character (.). Note that the return value doesn't indicate whether decimal separators are enabled.

See also: -·**setDecimalSeparator:**

format

-·(NSString *)**format**

Returns an NSString containing the format being used by the receiver.

See also: -·**setFormat:**

hasThousandSeparators

-·(BOOL)**hasThousandSeparators**

Returns YES to indicate that the receiver's format includes thousand separators, NO otherwise. The default is NO.

See also: -·**setHasThousandSeparators:**

localizesFormat

-·(BOOL)**localizesFormat**

Returns YES to indicate that the receiver localizes formats, NO otherwise. The default is NO.

See also: -·**setLocalizesFormat:**

maximum

-·(NSDecimalNumber *)**maximum**

Returns the highest number that is allowed as input by the receiver.

See also: -·**setMaximum:**

minimum

-·(NSDecimalNumber *)**minimum**

Returns the lowest number that is allowed as input by the receiver.

See also: -·**setMinimum:**

negativeFormat

-·(NSString *)**negativeFormat**

Returns an NSString containing the format used by the receiver to display negative numbers.

See also: -·**setNegativeFormat:**, -·**setFormat:**

positiveFormat

-·(NSString *)**positiveFormat**

Returns an NSString containing the format used by the receiver to display positive numbers.

See also: -·**setPositiveFormat:**, -·**setFormat:**

roundingBehavior

-·(NSDecimalNumberHandler *)**roundingBehavior**

Returns an NSDecimalNumberHandler object to indicate the rounding behavior used by the receiver.

See also: -·**setRoundingBehavior:**

setAllowsFloats:

-·(void)**setAllowsFloats:**(BOOL)*flag*

Sets according to *flag* whether the receiver allows as input floating point values (that is, values that include the period character (.)). By default, floating point values are allowed as input.

See also: -·**allowsFloats**

setAttributedStringForNil:

-·(void)**setAttributedStringForNil:**(NSAttributedString *)*newAttributedString*

Sets to *newAttributedString* the NSAttributedString the receiver uses to display **nil** values.

See also: -·attributedStringForNil

setAttributedStringForNotANumber:

-·(void)**setAttributedStringForNotANumber:**(NSAttributedString *)*newAttributedString*

Sets to *newAttributedString* the NSAttributedString the receiver uses to display ªnot a numberº values.

See also: -·attributedStringForNotANumber

setAttributedStringForZero:

-·(void)**setAttributedStringForZero:**(NSAttributedString *)*newAttributedString*

Sets to *newAttributedString* the NSAttributedString the receiver uses to display zero values.

See also: -·attributedStringForZero

setDecimalSeparator:

-·(void)**setDecimalSeparator:**(NSString *)*newSeparator*

Sets to *newSeparator* the character the receiver uses as a decimal separator. If *newSeparator* contains multiple characters, only the first one is used. If you don't have decimal separators enabled through another means (such as **setFormat:**), using this method enables them.

See also: -·decimalSeparator

setFormat:

-·(void)**setFormat:**(NSString *)*aFormat*

Sets the receiver's format to the string *aFormat*. *aFormat* can consist of one, two or three parts separated by `;'. The first part of the string represents the positive format, the second part of the string represents the zero value, and the last part of the string represents the negative format. If the string just has two parts, the first one becomes the positive format, and the second one becomes the negative format. If the string just has one part, it becomes the positive format, and default formats are provided for zero and negative values based on the positive format. For more discussion of this subject, see the section ªCreating an Instance of NSNumberFormatterº in the Class Description.

For example, the following code excerpt shows the three different approaches for setting an NSNumberFormatter object's format using **setFormat:**:

```
NSNumberFormatter *numberFormatter =
[[[NSNumberFormatter alloc] init] autorelease];
```

```
// specify just positive format
[numberFormatter setFormat:@"$#,##0.00"];

// specify positive and negative formats
[numberFormatter setFormat:@"$#,##0.00;($#,##0.00)"];

// specify positive, zero, and negative formats
[numberFormatter setFormat:@"$#,###.00;0.00;($#,##0.00)"];
```

See also: -·**format**

setHasThousandSeparators:

-·(void)**setHasThousandSeparators:**(BOOL)*flag*

Sets according to *flag* whether the receiver uses thousand separators. When *flag* is NO, thousand separators are disabled for both positive and negative formats (even if you've set them through another means, such as **setFormat:**). When *flag* is YES, thousand separators are used. In addition to using this method to add thousand separators to your format, you can also use it to disable thousand separators if you've set them using another method. The default is NO (though you in effect change this setting to YES when you set thousand separators through any means, such as **setFormat:**).

See also: -·**hasThousandSeparators**

setLocalizesFormat:

-·(void)**setLocalizesFormat:**(BOOL)*flag*

Sets according to *flag* whether the dollar sign character ($), decimal separator character (.), and thousand separator character (,) are converted to appropriately localized characters as specified by the user's localization preference. While this feature may be useful in certain types of applications, it's probably more likely that you would tie a particular application to a particular currency (that is, that you would ªhard-codeº the currency symbol and separators instead of having them dynamically change based on the user's configuration). The reason for this, of course, is that NSNumberFormatter doesn't perform currency conversions, it just formats numeric data. You wouldn't want one user interpreting the value ª56324º as US currency and another user who's accessing the same data interpreting it as Japanese currency, simply based on each user's localization preferences.

See also: -·**localizesFormat**

setMaximum:

-·(void)**setMaximum:**(NSDecimalNumber *)*aMaximum*

Sets to *aMaximum* the highest number the receiver allows as input.

See also: -·**maximum**

setMinimum:

-·(void)**setMinimum:**(NSDecimalNumber *)*aMinimum*

Sets to *aMinimum* the lowest number the receiver allows as input.

See also: -·**setMinimum:**

setNegativeFormat:

-·(void)**setNegativeFormat:**(NSString *)*aFormat*

Sets to *aFormat* the format the receiver uses to display negative values.

See also: -·**negativeFormat**, -·**setFormat:**

setPositiveFormat:

-·(void)**setPositiveFormat:**(NSString *)*aFormat*

Sets to *aFormat* the format the receiver uses to display positive values.

See also: -·**positiveFormat**, -·**setFormat:**

setRoundingBehavior:

-·(void)**setRoundingBehavior:**(NSDecimalNumberHandler *)*newRoundingBehavior*

Sets to *newRoundingBehavior* the rounding behavior used by the receiver.

See also: -·**roundingBehavior**

setTextAttributesForNegativeValues:

-·(void)**setTextAttributesForNegativeValues:**(NSDictionary *)*newAttributes*

Sets to *newAttributes* the text attributes to be used in displaying negative values. For example, this code excerpt causes negative values to be displayed in red:

```
NSNumberFormatter *numberFormatter =
[[[NSNumberFormatter alloc] init] autorelease];
NSMutableDictionary *newAttrs = [NSMutableDictionary dictionary];

[numberFormatter setFormat:@"$#,##0.00;($#,##0.00)"];
[newAttrs setObject:[NSColor redColor] forKey:@"NSColor"];
[numberFormatter setTextAttributesForNegativeValues:newAttrs];
[[textField cell] setFormatter:numberFormatter];
```

An even simpler way to cause negative values to be displayed in red is to include the constant [Red] in your format string, for example:

```
[numberFormatter setFormat:@"$#,##0.00;[Red]($#,##0.00)"];
```

Note: When you set a value's text attributes to use color, the color only appears when the value's cell doesn't have input focus. When the cell has input focus, the value is displayed in standard black.

See also: -·**textAttributesForNegativeValues**

setTextAttributesForPositiveValues:

-·(void)**setTextAttributesForPositiveValues:**(NSDictionary *)*newAttributes*

Sets to *newAttributes* the text attributes to be used in displaying positive values.

See also: -·**textAttributesForPositiveValues**

setThousandSeparator:

-·(void)**setThousandSeparator:**(NSString *)*newSeparator*

Sets to *newSeparator* the character the receiver uses as a thousand separator. If *newSeparator* contains multiple characters, only the first one is used. If you don't have thousand separators enabled through any other means (such as **setFormat:**), using this method enables them.

See also: -·**thousandSeparator**

textAttributesForNegativeValues

-·(NSDictionary *)**textAttributesForNegativeValues**

Returns an NSDictionary containing the text attributes that have been set for negative values.

See also: -·**setTextAttributesForNegativeValues:**

textAttributesForPositiveValues

-·(NSDictionary *)**textAttributesForPositiveValues**

Returns an NSDictionary containing the text attributes that have been set for positive values.

See also: -·**setTextAttributesForPositiveValues:**

thousandSeparator

-·(NSString *)**thousandSeparator**

Returns an NSString containing the character the receiver uses to represent thousand separators. By default this is the comma character (,). Note that the return value doesn't indicate whether thousand separators are enabled.

EOF 2.0 NT Oracle Adaptor Patch

This patch is version number 278.1. The Oracle Adaptor shipped with the EOF 2.0 release was version 278. You can find the version of the Oracle adaptor under the big red Oracle logo of the Oracle Login panel. This patch is **only** for use with EOF 2.0 installed on Windows NT as part of OPENSTEP or WebObjects.

The WebObjects Current Patch List, **TIL article 70037**, contains information on all available patches and workarounds for all versions of WebObjects, including EOF patches. The OPENSTEP Current Patch List, **TIL article 70033**, contains information on all available patches and workarounds for all versions of OPENSTEP, including EOF patches. Please read these documents if you're not sure which patches you need on your system.

This article has been archived and is no longer updated by Apple.

Installing the Oracle Adaptor Patch

Download the patch from:

ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/EOF/patches/2.0/OracleAdaptorPatch_NT.tar.gz

In order to install this patch, you will need to use gzip and gnutar to expand the attachment. You'll end up with a supplemental NextLibrary directory, which you can then copy into your existing NextLibrary directory. You need to log in as Administrator to install this patch.

Caution: The patch will replace **\\NextLibrary\\Executables\\OracleEOAdaptor.dll** and the entire **\\NextLibrary\\Frameworks\\OracleEOAdaptor.framework** directory, so you should take care to create a back up these items before installing over the top of them.

Assuming you have **OracleAdaptorPatch_NT.tar.gz** on c:/tmp and are using the Bourne Shell included with WebObjects or OPENSTEP Enterprise, here are the commands to install the patch:

```
$ cd $NEXT_ROOT
$ mv NextLibrary/Executables/OracleEOAdaptor.dll NextLibrary/Executables/OracleEOAdaptor.dll.bak
$ mv NextLibrary/Frameworks/OracleEOAdaptor.framework NextLibrary/Frameworks/OracleEOAdaptor.framework.bak
$ gzip -d -c c:/tmp/OracleAdaptorPatch_NT.tar.gz | gnutar -xvf -
```

EOF Oracle Adaptor Patch Release Notes

Problems Fixed in This Patch Update

The following problems have been fixed in this update:

Oracle EOAdaptor

References: 74355

Problems: The Oracle adaptor won't work with the Oracle 7.3 client libraries

Fix: This adaptor is actually linked against the OCIW32.LIB rather than the ORA72.LIB or the ORA73.LIB. Because the OCIW32.DLL doesn't change it's name each release, this means this adaptor should work against Oracle 7.2 and 7.3.

References: 74187

Problems: Every NSNumber or NSDecimalNumber that is created as a value fetched from the database is leaked.

Fix: The implementation of -[OracleNumberColumn fetchFromIndex:withZone:] no longer contains the extra retain call.

NeXTSTEP 3.3 Driver: Number Nine Imagine128 Series 2 Display

This document discusses a device driver for the NeXTSTEP operating system, version 3.3. This driver will not work with any version of OPENSTEP.
This article has been archived and is no longer updated by Apple.

Availability Information

An updated BETA version of this driver, version 3.32, is avaiable on Apple's FTP servers at:
ftp://ftp.info.apple.com/Apple_Support_Area/Apple_Software_Updates/MultiCountry/Enterprise/nextstep/drivers/beta/Num9Imagine128s2.pkg.compressed

Driver Name / Installer .pkg: Number9Imagine128S2DisplayDriver
Driver Type: Display
Driver Scope: Product Family
Supported Components: IBM RGB526 RAMDAC, IBM RGB528 RAMDAC, Number9 Imagine II, Number9 T2R
PC Bus / Interface Supported by Driver:** PCI

General Overview notes: This graphics driver is designed to support the Imagine 128 Series 2 and Revolution 3D adapters from Number Nine Visual Technology Inc.

This driver supports the use of 4MB, or 8MB of display memory. This driver also includes support for multi-headed displays.

Supported Products / Add-on Adapters:
Number9 Imagine 128 Series 2 (4MB) (90-228120-000)
Number9 Imagine 128 Series 2 (8MB) (90-228130)
Number9 Revolution 3D (4MB)
Number9 Revolution 3D (8MB)

Supported Products / Systems (ie integrated into PC System):

Special Features of Driver / Driver Notes:
This device driver provides information in the Configure application's help panel. Choose Info>Help from the Configure menu and scroll down to find this device driver's help topic.

Display Driver Details

Supported Connectors: 15-pin High Density (VGA)
Access Mode: Linear Framebuffer
Adapter Memory: 4MB VRAM, 4MB WRAM, 8MB VRAM, 8MB WRAM

Display Modes (Number in () after resolution indicates frame buffer size required)

32 Bit Color Modes:**
1024x768 (4MB+), 1152x864 (4MB+), 1280x1024(8MB+), 1600x1200(8MB+), 640x480 (2MB+), 800x600 (2MB+)

16 Bit Color Modes:**
1024x768 (2MB+), 1152x864 (2MB+), 1280x1024 (4MB+), 1600x1200 (4MB+), 640x480 (1MB+), 800x600 (1MB+)

8 Bit Color / Greyscale Modes:**
1024x768 (1MB+), 1152X864 (1MB+), 1280x1024 (2MB+), 1600x1200 (4MB+), 640X480 (1MB+), 800x600 (1MB+)

Known Problems

Some PCI machines will not start up if there is more than one Number Nine Imagine128 display adpter present. This is a BIOS limitation.

Driver Version Notes

3.30 - Initial Version - released only as beta
3.31 - Added support for Series 2 cards with integrated VGA controller. Added support for 8MB VRAM cards.
3.32 - Added support for Revolution 3D cards based on the T2R engine and WRAM display memory.

** - Indicates information that is inclusive of the entire capability of this driver. Not all devices supported by this driver may include all features listed. Check any available NeXTanswers and the hardware manual for the device for additional information.

Macintosh: Voicemail & Audiotex System Now Available

Do you know of any Macintosh product that handles DTMF (Dual Tone Multi Frequency) decoding, voice mail, and audiotex?

This article has been archived and is no longer updated by Apple.
TFLX, from Magnum Software, is a complete audiotex system for any 1MB Macintosh with a 20ns or faster hard disk.

TFLX is a combination hardware and software product. It connects to a serial port, has a sound digitizer, 1200 baud Hayes-compatible modem, serial port pass-through, and DTMF decoding. It can detect busy, ring, modem and fast busy recognition. The package is MultiFinder and AppleShare compatible and has a graphical user interface.

It also has database telemarketing capabilities, with keypad input for menu-driven operations.

The entire operation of the unit is programmable using Magnum's custom icon-oriented language.

A/UX: Recover a Missing or Corrupted System Folder (5/95)

If the System Folder, "/mac/sys/System Folder", of an A/UX user gets accidentally thrown away in the trash, what System Folder can be used to replace the original contents? Are there any special files?

This article has been archived and is no longer updated by Apple.
The A/UX command "systemfolder" can generate a clean personal Folder in the $HOME directory. The contents of the newly created personal System Folder will include generic files from the "/mac/lib/SystemFiles/private" and "/mac/lib/SystemFiles/shared" directories. Follow these steps:

1) Log on as "root"

2) Type the command "systemfolder"

3) If you receive the message, "System Folder '/System Folder' already exists - updating", type the command: mv "System Folder" "old system". Then type the command "systemfolder"

4) Logout as root and login as the user.

5) You have created a clean System Folder, and you can then copy the Extensions and Control Panels you want into the "/mac/sys/System Folder".

OPENSTEP 4.2 Release Notes: Application Kit

This document contains the following sections:

New Features in 4.2: High-level description of the changes in the Application Kit and related software between 4.1 and 4.2
New Features in 4.1: High-level description of the changes between 4.0 and 4.1
New Features in 4.0: High-level description of the changes between 3.3 and 4.0

Known Problems in This Release: List of important bugs in the Application Kit and related software in 4.2

Changes since 4.1: API and functionality changes in the Application Kit and related software between 4.1 and 4.2
Changes since 4.0: API and functionality changes between 4.0 and 4.1
Changes before 4.0: API and functionality changes between the prereleases of 4.0 and 4.0

This article has been archived and is no longer updated by Apple.

New Features in 4.2

Vertical SplitView

NSSplitView now supports vertical splits as well as horizontal splits.

ToolTips

It's now possible to add "tooltips" (short help messages which pop up as the user holds the mouse cursor over an item) to views. You can do this programmatically or via Interface Builder's Help panel.

Text Hyphenation & Justification

The text object now supports full justification & hyphenation. See the section "Changes since 4.1" for details.

ComboBoxCell

There is now a public NSComboBoxCell class. This allows you to use combo boxes in tableviews, among other things.

New Features in 4.1

ComboBox

The NSComboBox class has been added to the Application Kit. It offers similar functionality to the Combo Box control defined in the Microsoft° Windows, user interface.

Splash Screen

OPENSTEP for Windows now provides support for a "splash" screen in applications<basically a panel that comes up with a static image as the application is being launched. To use this feature, simply provide an 8-bit uncompressed bmp image named **Splash.bmp** as a resource in your application. You can make it localizable if you wish. (Thus the image will be either in *appname*.app/Resources or *appname*.app/Resources/*language*.lproj.) At launch time, the image will be loaded and displayed before any other initialization in the application, and will be removed from the screen before the first window is displayed.

For other changes in 4.1 please refer to the "Changes since 4.0" section below.

New Features in 4.0

OpenStep

OpenStep brings numerous API changes to the AppKit relative to Release 3.3. These changes and the tools provided for applications to convert to OpenStep are described in **/NextLibrary/Documentation/NextDev/Conversion/ConversionGuide**, available on OPENSTEP for Mach.

New Text System

4.0 includes a new text system composed of several different classes: NSTextView (front-end UI), NSTextStorage and NSAttributedString (back-end text storage), NSLayoutManager (management of text layout process and info), and NSTextContainer (description of text flow areas). These classes provide an open, powerful interface and allow text editing in multiple languages, using the Unicode standard. Please refer to the documentation for detailed info. An overview can be found in **/NextLibrary/Documentation/NextDev/TasksAndConcepts/ProgrammingTopics/TextOverview.rtfd** (Mach) or in the **/NextLibrary/Documentation/NextDev/TasksAndConcepts/Topics.hlp** (Windows). There is also a programming topic which describes some of the defaults that can be used to customize the new text system and how to remap or add to the standard supported keybindings. In addition to these notes, the source code to several text-specific examples, including the full source to TextEdit, can be found in the **/NextDeveloper/Examples/AppKit** directory.

TableView

TableView has been completely rewritten and moved into the AppKit. All four classes making up the new TableView are public and fully subclassable.

Keyboard UI

Keyboard access is now provided to most of the controls in the AppKit. For more information, see the separate Keyboard UI Release Notes.

Formatting and Validation

Cells may now be assigned arbitrary object values, which are converted into presentation strings by associated formatter objects. This allows the developer to directly set an NSDate, for instance, as the value of a cell. The cell's associated date formatter will present a localized string representation of the date to the user. The formatter objects, along with control delegates, can also perform validation on user-entered data, thereby restricting entries to valid ranges or quantities, for instance only allowing dates between January 1, 1995 and June 30, 1995.

Rich Text in Cells

NSCell and subclasses can now display and edit rich text. The rich text is specified via instances of NSAttributedString. The new formatting/validation API also includes support for attributed strings.

RulerView

NSRulerView is designed as a general-purpose ruler that can be associated with any scroll view and used by any view that's in the scroll view. It supports both horizontal and vertical rulers, allows arbitrary markers along the rule, and can accept an accessory view.

System Colors

New API has been added to access system-defined colors, such as the color of buttons, controls, text and text selection colors. On Windows, where the user can change the system colors at any point, these

colors will change at runtime to match the user's selection.

Help System

The AppKit's Help API has changed significantly. NSHelpPanel has been obsoleted in favor of a new class, NSHelpManager, which provides a more platform-independent approach to presenting help.

Known Problems in This Release

NSComboBox

Reference: 71826

Problem: NSComboBox should support keyboard interface

Description: NSComboBox does not support keyboard accelerators to open, dismiss, or navigate its popup list.

Workaround: None.

NSTableView

TableView does not yet have printing support.

Reference: 51731

Problem: TableView does not fully support keyboard ui

Description: Only simple tabbing between editable cells is implemted in TableView. Arrow keys do not affect selection.

Workaround: Override keyDown: in a subclass or in the owning window and change the selection accordingly.

Reference: 63967

Problem: Header and row height do not change relative to font size

Description: When the developer changes the font size of the header view cells or data cells in a TableView, the heights of the header view and rows do not change appropriately.

Workaround: Manually change the height of the header view and row height.

NSCell

Reference: 52511

Problem: **setUpFieldEditorAttributes:** called only when editing

Description: **setUpFieldEditorAttributes:** is not called when non-editable text is displayed in cells. This makes it difficult to change colors in custom subclasses of NSCell.

Workaround: To display colored text in cells, text fields or attributed string values may be used.

NSImage

Reference: 60413

Problem: JPEG TIFFs don't work on Windows.

Description: Because the imageserver process is not yet available under Windows, JPEG TIFFs cannot be loaded in.

Workaround: None. The images can be compressed using another compression scheme using tiffutil on OpenStep for Mach.

New Text System

Reference: 58479

Problem: Rotated text views don't do selection very well

Description: The selection drawing (at least) in a rotated NSTextView needs work. The selection is generally drawn too large and leaves pixels around.

Workaround: None. Avoid editable rotated NSTextViews for now.

Reference: 50123

Problem: Some features are currently unimplemented

Description: The following features are currently unimplemented: Tabs other than left, certain paragraph style attributes, scaled images.

Workaround: None.

Reference: 54951

Problem: Screen fragments in containers with holes

Description: If you attempt to create an NSTextContainer with holes such that one physical line can have multiple line fragments, there are still problems with erasing old drawing below the hole when text is deleted.

Workaround: None.

Reference: 49744

Problem: Images are not scaled in scaled text

Description: Using the standard NSTextAttachment class, the images appear at 100%.

Workaround: This problem can be fixed by using a custom attachment cell.

NSWindow

Reference: 71648

Problem: Closing a modal window or panel does not always end the modal session

Description: Closing a modal window or panel by clicking on the close box will not always end the modal session, leaving the application in a state where mouse clicks and key strokes are ignored. On Windows, modal panels often have a close box. This acts the same as a cancel button and, by default, clicking the close box while running modal will stop the modal session with the NSCancelButton return code. However, if the Window's delegate decides to control when the window should close by implementing

windowShouldClose:, then it is also up to the delegate to stop the modal session in windowWillClose:. On Mach, modal windows and panels rarely have a close box; if they do they must stop modal in windowWillClose:.

Workaround: On Windows, a window delegate implementing windowShouldClose should stop the modal session in windowWillClose:. On Mach, any modal window or panel with a close box should stop the modal session in windowWillClose:

Reference: 64988

Problem: NSBackingStoreNonretained don't work under Windows

Description: Under Windows, nonretained windows aren't implemented.

Workaround: Use retained or buffered windows instead.

Reference: 69973

Problem: Miniaturizing and then restoring a window under WindowsNT causes first responder to be lost

Description: When a window is miniaturized it loses track of its current first responder. When it is restored again, the first responder is not restored.

Workaround: You can use makeFirstResponder to set a first responder yourself or just make the user click something.

Drag/Drop

Reference: 60829

Problem: On Windows, **ignoreModifierKeysWhileDragging** is never invoked on drag source

Workaround: None.

Reference: 67620

Problem: On Windows **draggedImage** always returns nil.

Description: During a dragging session, the DraggingInfo will always return nil when queried for its draggedImage.

Workaround: None.

Reference: 63466

Problem: On Windows, the drag source's image offset is ignored

Description: Currently the dragged image will appear to the lower right of the cursor's hot spot.

Workaround: None.

NSFont

Reference: 61824

Problem: Microsoft's *WingDings* font is not supported well under OPENSTEP for Windows

Description: There isn't currently a Unicode mapping for any of the glyphs in it, even into the User Zone, so it works as any other "unknown" font (i.e., characters 0-255 are mapped directly to glyphs 0-255).

Workaround: None.

Keybord UI

Reference: 51182

Problem: AccesoryViews are not added to keyView loop

Description: When a panel supporting accessory views, such as the SavePanel, is brought on screen, the accessory views are not automatically added to the keyView loop.

Workaround: Add the accessory view to the keyView loop by hand using setNextKeyView: before brining the panel on screen.

Accessory Views

On Windows, the PageLayout panel does not yet support application supplied accessory views. Also on Windows, accessory views in the Open, Save and Print panels work only on NT 4.0, not NT 3.51.

Changes since 4.1

The following lists all the API changes and some of the bug fixes that were done in the Application Kit between 4.1 and 4.2.

Note that in your application if you use any API which was added in 4.2, your application might not run under 4.0 or 4.1. (If you are not deploying under a previous release, then this is not an issue.) You can catch some of the potential problems by defining **STRICT_40** or **STRICT_41** at compile time. These #defines are used in the Application and Foundation Kits to mark new API.

Similarly, if you rely on a bug fix done in 4.2, your application may not function correctly under 4.0 or 4.1. Make sure you test on your intended deployment platform.

NSSplitView

NSSplitView now supports vertical splits as well as horizontal splits:

```
- (void)setVertical:(BOOL)flag;
- (BOOL)isVertical;
```

In 4.2, splitview look & feel has been changed to be more Windows-like when running with the Windows interface style. There's no dimple, the split bar is thinner, and you get a resize cursor. The method **dividerThickness** returns the correct thickness of the bar.

ToolTips

Use the following API to set a tooltip on a view:

```
- (void)setToolTip:(NSString *)string;
- (NSString *)toolTip;
```

Specify a **nil** tooltip to cancel it.

Note that tooltips are currently not archived with views. However, if you set a tooltip in IB, they will be

correctly saved in the nib file, so this is not a serious issue.

NSComboBox

setFont: will now correctly change the font of the items in the drop down box. It will also call **setItemHeight:** to set the height of the items depending on the font size. If you wish to change the item height independently, you should call **setItemHeight:** after **setFont:**.

selectItemAtIndex: will now correctly set the item in the text field. It didn't do so in 4.1.

The formatter on a combo box will now be used in formatting items in the combo box in addition to the item in the text field.

NSApplication

Applications will now be properly terminated on Windows upon logoff or shutdown. This means the application delegate will get **applicationShouldTerminate:**, and if it answers NO, the shutdown will be cancelled.

Support for "hide" has been added to OPENSTEP for Windows. The default menu item for this is "Minimize All" under the "Windows" menu (with ctrl-h as the key equivalent). It is added there automatically by the kit (if not there). You can prevent this with the **NSDontAddMinimizeAllMenuItem** default. If you need to do this for your application, simply register this default at startup. Otherwise, like all defaults, users can also set this themselves.

In 4.0 and 4.1, the Application Kit erroneously called **setlocale**() to cause all C library functions to work in an localized way. The main impact of this was in European Windows systems, where primitives such as sprintf() started working in a localized fashion (expecting "," as decimal separator, for instance). This broke NSScanner's parsing of floating point numbers, and caused the infamous "red Project Builder windows on European Windows in certain cases" problem.

In 4.2, this bug has been fixed; the Application Kit no longer calls setlocale(). This should have no impact on Mach (where the operations of these functions were independent of the setlocale() call). On Windows this change means that sprintf(), etc will no longer by default work in a localized fashion. OPENSTEP-based objects will keep on working correctly with the appropriate locale info, so this hopefully has very little impact. Note that developers should avoid calling setlocale() themselves (or if they do, they should do it temporarily and restore the setting once they're done).

NSLayoutManager

The following API has been added to support hyphenation:

```
- (void)setHyphenationFactor:(float)factor;
- (float)hyphenationFactor;
```

Factor should be a float in the range 0.0-1.0. Whenever (width of the real contents of the line) / (the line fragment width) is below this value, hyphenation will be attempted when laying out the line. By default, the value is 0, meaning hyphenation is off. 1.0 causes hyphenation to be always attempted. Note that hyphenation will slow down text layout and increase memory usage, so it should be used sparingly.

You can save the hyphenation factor in an RTF file by specifying a value for **@"HyphenationFactor"** in the document attributes dictionary.

NSTextView

The following method has been added as the default target of the "Justify" menu item to allow full justification:

- (void)alignJustified:(id)sender;

NSOpenPanel

The open and save panels now allow directory selection on Windows. In addition, the open panel will correctly filter files to display only those with the specified extension (the "All Files" option lets the user override this).

NSView

In 4.2, tracking rects can be assigned to a view even if the window the view is in is deferred and has not been created yet. Note that this already worked on OPENSTEP for Windows in 4.1 but didn't on OPENSTEP for Mach. If you have a 4.2 application which uses tracking rects and it needs to run under 4.1, you should test it under 4.1 to make sure it does work. If not, you might have to delay your tracking rect creation or make your windows non-deferred.

Tracking rects now work in non-key windows on Windows. This was the case on Mach already.

NSColor

A bug in **decodeNXColor** which caused CMYK colors from 3.x archives to be read incorrectly in 4.0 and 4.1 has been fixed. (The colors were way off; instead of C, M, Y, K, the values 1-C, 1-M, 1-Y, and 1-K would be used.)

NSWindow

A bug causing certain windows on Windows to grow everytime they were brought on screen has been fixed.

On Windows in some cases mouse drag events could come before the mouse down; this has been fixed.

Ordering windows front would cause **NSWindowDidResizeNotification** to be sent on Windows. This is now done only when the window is resized.

Windows freed while minimized would leak their content views on Windows. This is no longer the case.

Changes since 4.0

The following list all the API changes and some of the bug fixes that were done in the Application Kit between 4.0 and 4.1.

NSApplication

IBOutlet and **IBAction** are now defined in the kit and automatically imported if you import **AppKit.h**. You can remove your own custom definitions of these (if you had any).

The **hide:** method has been changed to do nothing on Windows.

On Windows, **[NSApplication init]** (called by **sharedApplication**) changes the current directory to the root of the drive from which the application is launched. This is done in order to avoid problems associated with the application starting off in random places (such as the directory of a file-wrapper, when launched by double-clicking on a file in a file-wrapper). On consequence of this is that if your application changes the current directory in the **main()** function, this change will be overridden as soon as you call **sharedApplication**.

The default value of the **NSUseRunningCopy** command line option has been changed to YES. This means that anytime you cause a second copy of the application to be launched, it will connect you to the already running copy. You should also If you wish to run multiple copies of an application, you

should use "-NSUseRunningCopy NO". You might need this if you need to debug a new instance of the application while it's already running.

Another change is that all command line options which are not defaults options (meaning a pair of arguments where the first one starts with a "-") are now treated as file names to be opened, as if they were prefixed with -NSOpen.

As a result of these two changes, you can now associate documents with OPENSTEP apps on Windows simply by providing the location of the app. The default command line provided by the Explorer will be enough to open documents and also connect to a running copy of the application, if there is one.

NSWindow

In OPENSTEP for Windows, document edited state is now indicated in the title bar by prefixing the title with an asterisk. OPENSTEP for Mach still uses a broken "X".

Tracking rects are now implemented on Windows.

The following are not actually changes since 4.1, but are a couple things to be aware of concerning NSWindows in OPENSTEP for Windows.

· Under Windows, the frameRect and contentRect are currently the same size. The frameRect of an NSWindow under OPENSTEP for WIndows NT does NOT include the title bar, menu bar, resize border, etc...

· Under Windows, the contentView while a window is miniaturized is a NSImageView, not the original contentView. The contentView is restored when the window is deminiaturized. This is necessary because under some versions of Windows NT, the same actual window is used when the window is full size or miniaturized. It is just moved and resized when miniaturing or restoring. Since most content views are not prepared to size themselves that small, the content view is removed from the window while it miniaturizes and is restored when the window is restored.

NSTableView

A new notification, **NSTableViewSelectionIsChangingNotification**, and a corresponding delegate method, **tableViewSelectionIsChanging:**, have been added to NSTableView. The existing **NSTableViewSelectionDidChangeNotification** is only sent after the user has moused up when changing a selection. The new notification is sent while the selection is changing.

NSSavePanel

The save panel will now put up an alert letting you confirm before you replace an existing file.

NSInputServer

The following methods were added to NSInputServer. They are sent by current input manager when the application changes state so that the server can update its concept of who's current. The actually "active" sender is the last one to have sent a **senderDidBecomeActive:** message. These methods may not arrive in the expected order.

```
- (void)senderDidBecomeActive:(id)sender;
- (void)senderDidResignActive:(id)sender;
```

This method is sent by input manager when the conversation within a particular sender changes:

```
- (void)activeConversationWillChange:(id)sender oldConversation:(long)conv newConversation:(long)new;
```

NSTextView

To allow entering a character without an appropriate keyboard, you can now use the Alt key in conjunction with the digit keys from the keypad. While holding down the Alt key, type the index of the desired character in the encoding of the current font (in most cases this will be the NEXTSTEP encoding). The appropriate character will be inserted into the text when the Alt key is released.

NSWorkspace

The **openFile:withApplication:** will now correctly open the file with the specified application. In 4.0 this method always returned NO when an application name was supplied.

OPENSTEP for Window now contains an "open" command. Like on Mach, "open filename" will open the specified file in its registered application. You can also use the "-e" flag to open the file in TextEdit or the "-a" flag to launch an application.

NSAttributedString

If supplied a plain text file, the **initWithPath:documentAttributes:** method will now go ahead and still create an attributed string from the plain text contents. Note that if the file looks like an RTF file (has the appropriate magic header), but fails to open, the method will still return nil.

NSColor

Unarchived NSColors and NSColors created with **colorWithCalibratedRed:green:blue:alpha:** and **colorWithCalibratedWhite:alpha:** will be replaced by the cached and uniqued colors returned by methods such as [NSColor whiteColor] if they are exactly the same. In some cases this will greatly reduce the number of colors created at runtime and speed up certain operations. However, in the unlikely event that this causes problems in your application, or prevents your 4.0 application from running correctly under 4.1, you can set the **NSCachedColorConversion** default to NO.

System colors (such as those returned by [NSColor controlColor]) have been improved to generate colors which match those used by Windows. Under 8-bit color this should result in a visible improvement in certain color schemes.

Changes before 4.0

There are tops scripts to assist PR1 to PR2 and PR2 to 4.0 migration. Many of the API changes that have happened between prereleases can be automatically applied to your code with these commands:

```
tops -semiverbose -scriptfile /NextDeveloper/OpenStepConversion/ConversionScripts/PR1toPR2.tops *.[mchCM] *.psw *.pswm

tops -semiverbose -scriptfile /NextDeveloper/OpenStepConversion/ConversionScripts/PR2to40.tops *.[mchCM] *.psw *.pswm
```

Formatting and Validation

NSFormatter and NSDateFormatter have moved into the Foundation Kit. FoundationKit now also includes a number formatter. Imports of <AppKit/NSFormatter.h> or <AppKit/NSDateFormatter.h> will need to be changed to import the corresponding file from Foundation; imports of <AppKit/AppKit.h> don't need to be changed. The tops script mentioned above takes care of this. Also, a new NSNumberFormatter has been added.

The control delegate message **control:validateObject:** has been changed to **control:isValidObject:**.

NSApplication

NSApplication defines a new delegate method similar to **-application:openFile:** called

```
-(void)application:(NSApplication *)app printFile:(NSString *)path
```

Upon launching, an application scans its command line arguments for -NSOpen and, now, -NSPrint arguments. These arguments are followed by the path to a file to open or print respectively. NSApplication sends the above messages to its delegate if it responds in this way for the files specified on the command line. These messages are also invoked in response to Speaker/Listener interaction, but this aspect is perhaps less interesting to developers.

This new message (and the new command-line argument -NSPrint) is supported on both Mach and Windows.

Under Windows NT, when you install OPENSTEP, Explorer associations are automatically created for each file extension that the OPENSTEP applications claim. The file-type's icon is associated with its extension and Open and Print commands are registered as well. These commands work through the new command-line options, and can be accessed through Explorer's right-mouse context menu. So, for example, right clicking an RTF file in Explorer will give you a menu that includes both Open and Print as well as some other stuff. Choosing Open or Print will cause TextEdit to open or print the file. Open is registered as the default command for these file extensions, so double-clicking an RTF file will open it in TextEdit.

A new notification, **NSApplicationWillTerminateNotification,** has been added to OpenStep. It is sent before the Application's **terminate** method after **applicationShouldTerminate** is queried.

A Windows-specific method has been added to allow access to the Windows application handle. This will only be of interest to developers calling the Win32 API directly. (Arguments that varioius types of Windows handles are declared as void currently to avoid polluting the namespace with the vast amount of un-prefixed names in the Windows system headers.)

```
- (void * /*HINSTANCE*/)applicationHandle;
```

A Windows-specific method has been added to allow developers to look up an NSWindow object given a Windows HWND handle. This will only be of interest to developers calling the Win32 API directly.

```
- (NSWindow *)windowWithWindowHandle:(void * /*HWND*/)hWnd;
```

A Windows-specific method has been added for developers who choose to implement their own WinMain() function If you do so, call the method below before doing any other AppKit calls. The arguments are those passed to WinMain() from the system.

```
+ (void)setApplicationHandle:(void * /*HINSTANCE*/)hInstance
previousHandle:(void * /*HINSTANCE*/)PrevInstance
commandLine:(NSString *)cmdLine
show:(int)cmdShow;
```

NSTableView

The table view has a new mode where it resizes all the columns, not just the last one, to fill the scroll view. In this mode, if the table view fits exactly into its scroll view, and is then grown, it will grow all of its resizable columns to keep itself the size of the scroll view. Here are the new methods to enable this:

```
- (void)setAutoresizesAllColumnsToFit:(BOOL)flag;
- (BOOL)autoresizesAllColumnsToFit;
```

While tracking a cell or performing the table view's action, one may discover what cell was clicked on to cause the action to perform with these additional methods:

```
- (int)clickedColumn;
- (int)clickedRow;
```

NSAttributedString

Parts of NSAttributedString and NSMutableAttributedString have moved into the Foundation Kit. Just

using Foundation, without the Application Kit, you can create and manipulate attributed strings; however you do not have access to the standard attribute types such as color, font, and paragraph style. The rest of the attributed string functionality is provided by categories in Application Kit.

The following names have changed in NSAttributedString:

```
NSAttributedStringEditedAttributes -> NSTextStorageEditedAttributes
NSAttributedStringEditedCharacters -> NSTextStorageEditedCharacters
```

The following methods to read RTF:

```
+ (NSAttributedString *)attributedStringFromRTF:(NSData *)rtfData;
+ (NSAttributedString *)attributedStringFromRTFD:(NSData *)rtfData;
+ (NSAttributedString *)attributedStringFromRTFDFile:(NSString *)rtfdPath;
```

have been replaced by:

```
- (id)initWithRTF:(NSData *)data documentAttributes:(NSDictionary **)dict;
- (id)initWithRTFD:(NSData *)data documentAttributes:(NSDictionary **)dict;
- (id)initWithPath:(NSString *)path documentAttributes:(NSDictionary **)dict;
- (id)initWithRTFDFileWrapper:(NSFileWrapper *)wrapper documentAttributes:(NSDictionary **)dict;
```

The optional dict argument is for returning document-wide attributes, which currently include "PaperSize", "LeftMargin", "RightMargin", "TopMargin", and "BottomMargin". Pass NULL for dict if you don't care about these.

The following methods to write RTF:

```
- (NSData *)RTFFromRange:(NSRange)range;
- (NSData *)RTFDFromRange:(NSRange)range;
- (BOOL)writeRTFDToFile:(NSString *)path atomically:(BOOL)flag;
```

have been replaced by:

```
- (NSData *)RTFFromRange:(NSRange)range documentAttributes:(NSDictionary *)dict;
- (NSData *)RTFDFromRange:(NSRange)range documentAttributes:(NSDictionary *)dict;
- (NSFileWrapper *)RTFDFileWrapperFromRange:(NSRange)range documentAttributes:(NSDictionary *)dict;
```

Pass nil for dict if you don't want to specify any of the document attributes.

To write RTFD to file you will need to send **writeToFile:atomically:updateFilenames:** to the NSFileWrapper you get back from **RTFDFileWrapperFromRange:documentAttributes:**. The updateFilenames: flag should usually be YES (unless you are doing a "Save To").

The following method names are changed in NSMutableAttributedString:

Before:

```
- (void)fixAttributesAfterEditingRange:(NSRange)range;
- (void)fixFontAttributeAfterEditingRange:(NSRange)range;
- (void)fixParagraphStyleAfterEditingRange:(NSRange)range;
- (void)fixAttachmentAfterEditingRange:(NSRange)range;
```

After:

```
- (void)fixAttributesInRange:(NSRange)range;
- (void)fixFontAttributeInRange:(NSRange)range;
- (void)fixParagraphStyleAttributeInRange:(NSRange)range;
- (void)fixAttachmentAttributeInRange:(NSRange)range;
```

The value of **NSAttachmentCharacter** has been changed from 0xF6FF to 0xFFFC to match the one proposed in the Unicode standard. Code which uses this value will need to be recompiled; places where this value is archived explicitly might need to check for the old value. (RTF files did archive this value, so no need for changes there.) If the old value ever appears in an attributed string at runtime, the new value will be used, and a warning will be generated (single warning per app session).

The method **updateAttachmentsFromPath:** has been added to NSMutableAttributedString to allow updating the file name information in all the attachments in the attributed string.

NSImage

NSImage now understands the bmp, ico, and cur image formats. ico and cur files with multiple images will be loaded as images with multiple representations. Typically these representations will have different sizes (unlike multiple-representation tiffs, which have different depths); by default, NSImage will choose the largest image when compositing.

Windows-specific methods have been added to NSImage and NSBitmapImageRep which allow creation of these objects from a Windows icon handle or bitmap handle. These will only be of interest to developers calling the Win32 API directly.

```
- (id)initWithIconHandle:(void * /* HICON */)icon;
- (id)initWithBitmapHandle:(void * /* HBITMAP */)bitmap;
```

setFlipped: and **flipped** have been brought back into the API.

Compositing Operation name changes

Some of the constants declared by DPSClient for various compositing operations have had their names corrected:

Old Name	New Name
NSCompositeDataOver	NSCompositeDestinationOver
NSCompositeDataInreplace	NSCompositeDestinationIn
NSCompositeDataOut	NSCompositeDestinationOut
NSCompositeDataAtop	NSCompositeDestinationAtop

NSCursor

In order to make NSCursor immutable, the following methods:

```
- (id)initWithImage:(NSImage *)newImage;
- (void)setImage:(NSImage *)newImage;
- (void)setHotSpot:(NSPoint)spot;
```

have been replaced by:

```
- (id)initWithImage:(NSImage *)newImage hotSpot:(NSPoint)aPoint;
- (id)initWithImage:(NSImage *)newImage
foregroundColorHint:(NSColor *)fg
backgroundColorHint:(NSColor *)bg
hotSpot:(NSPoint)hotSpot;
```

The color hints in the latter method are ignored in OPENSTEP for Windows and for Mach.

The **initWithImage:** and **setImage:** methods are somewhat generic and hard to detect, so the tops script might fail to catch all your uses.

Another change in NSCursor since PR2 is the support for custom cursor selections on Windows. OPENSTEP applications will use the correct arrow and I-beam cursors where applicable. If you ask for the image of one of these standard cursors on OPENSTEP for Windows, you will get back the correct image used by the system. You should note that the size of this image may be different than the traditional 16x16 used on Mach. For animated cursors you will simply get back the first frame.

NSText

The following method names are changed in the NSText API:

Before:

```
- (NSString *)text;
- (void)setText:(NSString *)string;
- (void)setText:(NSString *)string range:(NSRange)range;
- (void)replaceRange:(NSRange)range withRTF:(NSData *)rtfData;
- (void)replaceRange:(NSRange)range withRTFD:(NSData *)rtfdData;
- (void)setColor:(NSColor *)color ofRange:(NSRange)range;
- (void)setFont:(NSFont *)font ofRange:(NSRange)range;
```

After:

```
- (NSString *)string;
- (void)setString:(NSString *)string;
- (void)replaceCharactersInRange:(NSRange)range withString:(NSString *)aString;
- (void)replaceCharactersInRange:(NSRange)range withRTF:(NSData *)rtfData;
- (void)replaceCharactersInRange:(NSRange)range withRTFD:(NSData *)rtfdData;
- (void)setTextColor:(NSColor *)color range:(NSRange)range;
- (void)setFont:(NSFont *)font range:(NSRange)range;
```

NSTextView

The following methods are added to NSTextView:

```
- (void)pasteAsPlainText:(id)sender;
- (void)pasteAsRichText:(id)sender;

- (NSPoint)textContainerOrigin;
- (void)invalidateTextContainerOrigin;

- (NSRange)rangeForUserTextChange;
- (NSRange)rangeForUserCharacterAttributeChange;
- (NSRange)rangeForUserParagraphAttributeChange;

- (BOOL)smartInsertDeleteEnabled;
- (void)setSmartInsertDeleteEnabled:(BOOL)flag;
- (NSRange)smartDeleteRangeForProposedRange:(NSRange)proposedCharRange;
- (void)smartInsertForString:(NSString *)pasteString replacingRange:(NSRange)charRangeToReplace
beforeString:(NSString **)beforeString afterString:(NSString **)afterString;
```

The following method names are changed in the NSTextView API to allow richer specification of selected text attributes:

Before:

```
- (void)setSelectionColor:(NSColor *)color;
- (NSColor *)selectionColor;
```

After:

```
- (void)setSelectedTextAttributes:(NSDictionary *)attributeDictionary;
- (NSDictionary *)selectedTextAttributes;
```

Underlining is now supported in the new text system; **NSSingleUnderlineStyle** has been added as a possible value for the **NSUnderlineStyleAttributeName** attribute.

The delegate method **textView:clickedOnCell:inRect:** has been added to indicate single-clicks on text attachments.

The method **attachmentForDraggedFilename:** has been removed from the API.

NSTextStorage

NSTextStorage now sends out notification messages after edits:

```
NSTextStorageWillProcessEditingNotification
NSTextStorageDidProcessEditingNotification
```

It also has a delegate who gets the following messages:

```
- (void)textStorageWillProcessEditing:(NSNotification *)notification;
- (void)textStorageDidProcessEditing:(NSNotification *)notification;
```

These methods are called during post-edit processing (basically after **endEditing** has been called, or, if endEditing was not in effect, after each edit that causes **edited:range:changeInLength:**). The first notification is sent before attributes are fixed, the second is sent after the attributes are fixed, but before the layout managers are notified. During the execution of **textStorageWillProcessEditing:** the delegate can change the attributed string all it wants; during **textStorageDidProcessEditing:** it should refrain from changing the character contents. The changes done by the delegate will not cause further notifications to be sent. However, during the execution of these methods and notifications the delegate and the observers can obtain information about what's changed via the following methods:

```
- (unsigned)editedMask;
- (NSRange)editedRange;
- (int)changeInLength;
```

NSTextStorage now also has a clear funnel point for all post-edit processing:

```
- (void)processEditing;
```

This method sends the above notification methods, calls **fixAttributesInRange:**, and informs the layout managers of the changes.

The following methods, now much less useful, have been removed from the API:

```
- (void)verifyEdited:(unsigned)mask range:(NSRange)range changeInLength:(int)delta;
- (void)notifyEdited:(unsigned)mask range:(NSRange)range changeInLength:(int)delta
invalidatedRange:(NSRange)invRange;
```

Subclassers, note: NSTextStorage is now a semi-abstract class. It implements change management (**beginEditing**/**endEditing**), verification of attributes, and layout management notification. The one aspect it does not implement is the actual attributed string storage--this is left up to the subclassers, which need to override the two NSMutableAttributedString primitives **replaceCharactersInRange:withString:** and **setAttributes:range:**. These primitives should perform the change then call **edited:range:changeInLength:** to get everything else to happen.

Here is a sample NSTextStorage subclasser:

```
@implementation SimpleTextStorage

/* Provide your own init methods, whatever you wish... Here we provide one (initWithAttributedString:) and override the DI from super
(init). */

- (id)initWithAttributedString:(NSAttributedString *)attrStr {
if (self = [super init]) {
contents = attrStr ? [attrStr mutableCopyWithZone:[self zone]] :
[[NSMutableAttributedString allocWithZone:[self zone]] init];
}
return self;
}

- init {
return [self initWithAttributedString:nil];
}

- (void)dealloc {
[contents release];
[super dealloc];
}

/* The next set of methods are the primitives for attributed and mutable attributed string... */

- (NSString *)string {
return [contents string];
}
```

```
- (NSDictionary *)attributesAtIndex:(unsigned)location effectiveRange:(NSRange *)range {
return [contents attributesAtIndex:location effectiveRange:range];
}

/* In the mutable primitives (and any non-primitives which are overridden and which don't go through the primitives), we need to call
edited:range:changeInLength: to allow the text storage change management to do its job. */

- (void)replaceCharactersInRange:(NSRange)range withString:(NSString *)str {
[contents replaceCharactersInRange:range withString:str];
[self edited:NSAttributedStringEditedCharacters
range:range
changeInLength:(int)[str length] - (int)range.length];
}

- (void)setAttributes:(NSDictionary *)attrs range:(NSRange)range {
[contents setAttributes:attrs range:range];
[self edited:NSAttributedStringEditedAttributes range:range changeInLength:0];
}

@end
```

NSFileWrapper

A new public class has been added to the AppKit. NSFileWrapper provides support for the concept of a document wrapper (like a .rtfd, .nib, or many other NEXTSTEP file types). The new text system uses this class to handle RTFD documents, but it is designed to be generally useful. It handles reading and writing file packages in the file system as well as serializing them for use with the Pasteboard. See the General Reference for details.

NSTextAttachment

The following changes in NSTextAttachment take advantage of NSFileWrapper:

Before:

```
- (id)initWithContentsOfFile:(NSString *)path;
- (BOOL)writeToFile:(NSString *)path atomically:(BOOL)flag;
```

After:

```
- (id)initWithFileWrapper:(NSFileWrapper *)fileWrapper; /* Designated initializer */
- (void)setFileWrapper:(NSFileWrapper *)fileWrapper;
- (NSFileWrapper *)fileWrapper;
```

The **name** and **setName:** methods have also been removed from the API.

NSParagraphStyle

Subclassers, note: **NSParagraphStyle** and **NSMutableParagraphStyle** used to be abstract; they are now concrete.

setParagraphStyle: has been added to NSMutableParagraphStyle to allow setting all the values with one call.

NSRulerView/NSRulerMarker

The delegate method **rulerView:willSetClientView:** has been added to NSRulerView to give the existing client a chance to clean up.

The following method names are changed in NSRulerMarker:

Before:

```
- (void)setLocation:(float)location;
- (float)location;
- (id)initWithRulerView:(NSRulerView *)ruler location:(float)location image:(NSImage *)image imageOrigin:(NSPoint)imageOrigin;
```

After:
- (void)setMarkerLocation:(float)location;
- (float)markerLocation;
- (id)initWithRulerView:(NSRulerView *)ruler location:(float)location image:(NSImage *)image imageOrigin:(NSPoint)imageOrigin;

NSWorkspace

The following NSWorkspace methods will raise under OPENSTEP for Windows to indicate that they are not implemented (and the return value, being wrong, shouldn't be relied upon):

- (BOOL)fileSystemChanged;
- (BOOL)userDefaultsChanged;
- (NSArray *)mountedRemovableMedia;
- (NSArray *)mountNewRemovableMedia;

The following methods are no-ops:

- (void)checkForRemovableMedia;
- (void)findApplications;
- (void)hideOtherApplications;
- (void)noteUserDefaultsChanged;
- (void)noteFileSystemChanged;
- (BOOL)getFileSystemInfoForPath:isRemovable:isWritable:isUnmountable:description:type:;
- (int)extendPowerOffBy;
- (void)slideImage:(NSImage *)image from:(NSPoint)fromPoint to:(NSPoint)toPoint;

In addition, note that the **NSWorkspaceRecycleOperation** will currently remove the files in OPENSTEP for Windows.

NSBrowser

The width of columns are now dealt with as floats rather than ints to be consistent with the rest of the AppKit:

Before:
- (void)setMinColumnWidth:(int)columnWidth;
- (int)minColumnWidth;

After:
- (void)setMinColumnWidth:(float)columnWidth;
- (float)minColumnWidth;

A couple other api items changed names:

Before:
- (void)drawTitle:(NSString *)title inRect:(NSRect)aRect ofColumn:(int)column;
- (BOOL)browser:(NSBrowser *)sender selectCell:(NSString *)title inColumn:(int)column;

After:
- (void)drawTitleOfColumn:(int)column inRect:(NSRect)aRect;
- (BOOL)browser:(NSBrowser *)sender selectCellWithString:(NSString *)title inColumn:(int)column;

Selection may now be done by index as well as path. Previously the developer was forced to resort to NSMatrix apis when trying to select a row in a browser column by index. Now she may use:

- (void)selectRow:(int)row inColumn:(int)column;
- (int)selectedRowInColumn:(int)column;

And the following delegate method was added in parallel to allow the delegate to perform the selection:

- (BOOL)browser:(NSBrowser *)sender selectRow:(int)row inColumn:(int)column;

Alerts

Two pairs of new functions have been added to support the alert styles found in the Windows UI. **NSRunInformationalAlertPanel()** and **NSRunCriticalAlertPanel()** take the same paramenters as **NSRunAlertPanel()**, but on Windows they present an alert with the "informational" or "critcal" icons, respectively. On Windows **NSRunAlertPanel()** presents an alert with the "warning" icon. On Mach calling any of the three functions produces the same UI. Also note that on Windows alerts have no title, so the title argument to these functions is not displayed in the UI. In addition, **NSGetInformationalAlertPanel()** and **NSGetCriticalAlertPanel()** have been added, which have the same relationship to the existing **NSGetAlertPanel()**.

The function **NSRunLocalizedAlertPanel()** is removed from the API; use **NSRunAlertPanel()** with explicitly localized arguments instead.

Services

The API involved in vending services has changed in PR2. The need for two names to resolve a service provider has been removed. In PR1, services were advertised in the Info.plist using a combination of NSExecutable, and NSProviderName. The provider name is now obsolete, so you simply advertise a single name under the entry NSPortName. This entry has the same meaning as in 3.3 services. Usually NSPortName will be the name of your application as NSExecutable was (e.g. "Webster"). The following API changes have also been made:

· **registerServiceProvider:withName:** has been obsoleted. Use **setServicesProvider:**.
· **unregisterServiceProviderNamed:** has been obsolete. Use **setServicesProvider:nil**.

Two new functions, **NSRegisterServiceProvider()** and **NSUnregisterServicesProvider()** can be used to register service providers under a given name. These functions should only be used by service providers not creating an application object (filter services often fall into this category). The name argument should be the same as that specified by the NSPortName entry of the Info.plist. See the Services documentation for more details.

NSWindow

The following new methods control the resizing behavior of the window. The first pair are used to make a window resize in fixed increments. The second pair are used to make a window resize such that it maintains an aspect ratio.

```
- (void)setResizeIncrements:(NSSize)increments;
- (NSSize)resizeIncrements;
- (void)setAspectRatio:(NSSize)ratio;
- (NSSize)aspectRatio;
```

The following new methods provide an OpenStep alternative to the NEXTSTEP-specific feature of instance drawing. The first method saves away a part of the window's image. Typically after this step, some temporary drawing is done. The second method restores the previously saved image, undoing any drawing that has happened since it was saved. The third method releases the memory used to hold the saved image.

```
- (void)cacheImageInRect:(NSRect)aRect;
- (void)restoreCachedImage;
- (void)discardCachedImage;
```

The **fax:** method has been removed from the OpenStep specification, and is now specific to the Mach platform.

A Windows-specific method has been added to allow access to the Windows window handle of an

NSWindow object. This will only be of interest to developers calling the Win32 API directly.

```
- (void * /*HWND*/)windowHandle;
```

NSView

The following new method removes a view from its view hierarchy, without marking that the now exposed region in its superview needs redisplay. This can be useful when a view is temporaily swapped in so as to draw something on behalf of its superview.

```
- (void)removeFromSuperviewWithoutNeedingDisplay;
```

The following method was added in order to preserve the utility of panels that "become key only if needed" (the Font Panel, for example). This feature was defeated by the advent of increased keyboard accessibility to the UI, as nearly all widgets now accept becoming the first responder, which meant the panel would become key almost no matter where the user clicked. The following method is implemented by a widget to return YES if clicking on it should cause one of these panels to become key (which is the same role **acceptsFirstResponder** used to play in these panels).

```
- (BOOL)needsPanelToBecomeKey;
```

The **fax:** method has been removed from the OpenStep spec, and is now specific to the Mach platform.

The following API was removed because it was unused in any of the OPENSTEP products.

```
@interface NSView(NSRIBPrinting)
- (BOOL)canPrintRIB;
@end

typedef enum _NSPosition {
NSNoPosition = 0,
NSLeft = 1,
NSRight = 2,
NSTop = 3,
NSBottom = 4
} NSPosition;
```

A new method has been added to NSView, which is to be overridden by subclassers to find when their view is installed in a new superview.

```
- (void)viewWillMoveToSuperview:(NSView *)newSuperview;
```

Two new display methods have been added to round out the existing set.

```
- (void)displayIfNeededInRect:(NSRect)rect;
- (void)displayIfNeededInRectIgnoringOpacity:(NSRect)rect;
```

The **NSViewBoundsChangedNotification** notification present in PR1 has been added to the OpenStep spec.

Updating in NSApplication, NSWindow and DPSClient

Various updating mechanisms in the Application Kit are now driven by a new Foundation feature, where NSRunLoop will perform selectors registered by clients in a given order during it's next cycle. (See **performSelector:target:argument:order:modes:** in NSRunLoop.) The following constants represent these uses within the Application Kit:

NSUpdateWindowsRunLoopOrdering (500000)
All Windows are sent the update message. This is also the time when menu items are enabled and disabled.

NSDisplayWindowRunLoopOrdering (600000)

All Windows holding Views needing redisplay are given the chance to redraw.

NSResetCursorRectsRunLoopOrdering (700000)
If needed, cursor rectangles are reestablished.

DPSFlushContextRunLoopOrdering (800000)
The IPC channel to the Window Server is flushed, ensuring any buffered data is executed.

NSResponder

The **insertNewLine:** method was renamed to **insertNewline:**.

NSApplicationMain

The AppKit now provides a function NSApplicationMain() to take care of the initialization and startup of your application. This function is declared in NSApplication.h. Because of this, ProjectBuilder will now generate a trivial main function for your application:

```
#import <AppKit/NSApplication.h>

int main(int argc, const char *argv[]) {
NSApplicationMain(argc, argv);
}
```

Although developer's should not need access to the body of NSApplicationMain(), it is documented here in the rare case that it is necessary. If at all possible, avoid copying this code, as doing so may prevent your application from automatically inheriting features added in future releases.

```
int NSApplicationMain(int argc, const char *argv[]) {
NSAutoreleasePool * pool = [[NSAutoreleasePool alloc] init];
NSDictionary *info = [[NSBundle mainBundle] infoDictionary];
NSString *principalClassName = [info objectForKey: @"NSPrincipalClass"];
NSString *mainNibFile = [info objectForKey: @"NSMainNibFile"];

if (principalClassName) {
Class principalClass = NSClassFromString(principalClassName);
if (principalClass) {
[principalClass sharedApplication];
if ([NSBundle loadNibNamed: mainNibFile owner: NSApp]) {
[pool release];
[(NSApplication *)NSApp run];
[NSApp release];
exit(0);
}
else NSLog(@"Unable to load nib file: %@, exiting", mainNibFile);
}
else NSLog(@"Unable to find class: %@, exiting", principalClassName);
}
else NSLog(@"No NSPrincipalClass specified in info dictionary, exiting");
[NSApp release];
[pool release];
exit(1);
return 0;
}
```

NSHost

NSHost (or NXHost)'ing is supported only between OPENSTEP for Mach machines or from NEXTSTEP 3.x machines to OPENSTEP for Mach. You cannot run an OPENSTEP application NSHost'ed to a 3.x machine. NSHost'ing is also not supported on OPENSTEP for Windows.

ObjectLinks

ObjectLinks have been removed from the OpenStep specification, and in general the feature is not supported in OPENSTEP for Mach or Windows. The exception is that the following subset of the API may be used on either platform to walk through the linked data from documents written in NEXTSTEP 3.X:

```
@interface NSDataLinkManager : NSObject <NSCoding> {
- (id)initWithDelegate:(id)obj fromFile:(NSString *)path;
- (NSEnumerator *)sourceLinkEnumerator;
- (NSEnumerator *)destinationLinkEnumerator;
@end

@interface NSDataLink : NSObject <NSCopying, NSCoding>
- (NSArray *)types;
- (NSSelection *)sourceSelection;
- (NSSelection *)destinationSelection;
- (NSString *)sourceFilename;
- (NSString *)currentSourceFilename; - (NSString *)destinationFilename;
- (NSString *)sourceApplicationName;
- (NSString *)destinationApplicationName;
- (NSDataLinkManager *)manager;
- (NSDate *)lastUpdateTime;
- (NSDataLinkNumber)linkNumber;
- (NSDataLinkDisposition)disposition;
@end

@interface NSSelection : NSObject <NSCopying, NSCoding>
+ (NSSelection *)emptySelection;
+ (NSSelection *)allSelection;
+ (NSSelection *)currentSelection;
- (NSData *)descriptionData;
- (BOOL)isWellKnownSelection;
@end
```

Note that this API is a subset of the previously provided ObjectLinks API, with one exception: The **currentSourceFilename** method has been added to NSDataLink to allow the application to query the current location of the source file (whereas the **sourceFilename** method returns the original name).

-NSShowPS

On Windows NT, when apps are run with the arguments "-NSShowPS YES", they will produce a dump of their PostScript output in the file **$TEMP\\showps.txt** (where $TEMP is an environment variable usually containing "C:\\temp".

NSColor

The following methods have been added to NSColor:

```
@interface NSColor (NSDynamicSystemColors) // OpenStep/Mach: Windows Name:
+ (NSColor *)controlShadowColor; // darkGrayColor COLOR_3DSHADOW
+ (NSColor *)controlDarkShadowColor; // blackColor COLOR_3DDKSHADOW
+ (NSColor *)controlColor; // lightGrayColor COLOR_3DFACE
+ (NSColor *)controlHighlightColor; // lightGrayColor COLOR_3DLIGHT
+ (NSColor *)controlLightHighlightColor; // whiteColor COLOR_3DHILIGHT
+ (NSColor *)textColor; // blackColor COLOR_WINDOWTEXT
+ (NSColor *)textBackgroundColor; // whiteColor COLOR_WINDOW
+ (NSColor *)selectedTextColor; // blackColor COLOR_HIGHLIGHTTEXT
+ (NSColor *)selectedTextBackgroundColor; // lightGrayColor COLOR_HIGHLIGHT
+ (NSColor *)controlBackgroundColor; // lightGrayColor COLOR_WINDOW
+ (NSColor *)controlTextColor; // blackColor COLOR_BTNTEXT
+ (NSColor *)selectedControlTextColor; // blackColor COLOR_HIGHLIGHTTEXT
+ (NSColor *)selectedControlColor; // whiteColor COLOR_HIGHLIGHT
+ (NSColor *)scrollBarColor; // grayColor COLOR_SCROLLBAR
```

```
+ (NSColor *)gridColor; // grayColor COLOR_3DFACE

@end
```

These colors should be used by developers who want to create custom controls or subclass existing controls which honor the user's color preferences. For example, where

```
PSsetgray(NX_LTGRAY);
```

was used,

```
[[NSColor controlColor] set];
```

is now used.

These colors belong to their own color space, namely:

```
extern NSString *NSDynamicSystemColorSpace;
```

Since these colors may change dynamically, they do not respond to the component accessor methods declared in NSColor.h. To extract the components of a system color, you must use NSColor's **colorUsingColorSpaceName:** method to convert the color to a color space known to respond to the component accessor methods you need.

The following notification has been added which is sent when the system colors have been changed (such as through a system control panel interface):

```
extern NSString *NSSystemColorsDidChangeNotification;
```

The default **NSCMYKAdjust** is now YES by default. This basically enables the WindowServer's ability to use an enhanced algorithm for rendering device-dependent CMYK colors on an RGB device, resulting in a greater accuracy in the on-screen appearance of CMYK colors.

Applications can turn this off by registering this default with a NO value at startup time.

Platform specific resources

Under PR1 and PR2 including platform-specific versions of resource files (nibs, for instance), required Makefile kludgery and/or source changes. This is no longer necessary.

NSBundle has been changed so that when it fetches a resource, it will look in the directory where the resource was found one additional time to check for a platform-specific version. The platform specific versions are indicated by appending "*-platformname*" to the base name of the resource. Valid platform names include **winnt** and **nextstep**.

For example, to include a Windows-specific version of Doc.draw in your project, simply add it as Doc-winnt.draw. The call [bundle pathForResource:@"Doc" ofType:@"draw"] will find the latter under OPENSTEP for Windows. Similarly a Windows-specific version of Edit.nib can be added as Edit-winnt.nib.

Note that ProjectBuilder also provides ways to specify platform-specific app and document icons, paths, and build options.

NSMenu

The OpenStep spec was amended to make NSMenu a subclass of NSObject, not NSPanel, and to replace NSMenuCell with the NSMenuItem protocol. NeXT's OPENSTEP products also provide an NSMenuItem class which conforms to the NSMenuItem protocol.

NSMenu and NSMenuItem provide almost all of the functionality of the old classes, but some window

and cell specific features are no longer available. This change was motivated by the very different ways menus are handled on different operating systems (such as Microsoft Windows). See the headers for more detail.

The NSWindow and NSView have additional support for menus to support Microsoft Windows conventions. Each NSWindow can have its own menu bar or no menu bar at all. By default NSWindow objects have the application's main menu as their menu bar while NSPanels have no menu bar. Use -[NSWindow setMenu:] to set a different NSMenu to be used as the menu bar in an NSWindow. **setMenu:** in NSWindow only has an affect in OPENSTEP for Windows since on Mach, windows do not have menu bars, but the API does exist on both platforms.

NSViews can now have menus associated with them as well. An NSView's menu is used as a contextual popup menu accessed by right-clicking the view (this should be a familiar feature to users of Windows 95). By default an NSView has no contextual menu, but some AppKit objects will provide default context menus. Currently only NSTextView (and therefore also editable controls) have a default menu, but this is likely to change. You can set a menu to be used as the context menu for a view through -[NSView setMenu:]. Context menus currently only work on OPENSTEP for Windows.

Setting a menu for either a window or view on Mach has no affect, so there is no need to do this conditionally inside an #ifdef WIN32 or anything. Context menus for views may even be supported on Mach in a later release.

Interface Style

Some aspects of the new support for multiple interface styles (or UIs) have been made public.

The header NSInterfaceStyle.h is now public and can be used by developers writing classes that need to tailor their appearance to the current interface style (usually NSControl or NSView subclasses, but not always). The function **NSInterfaceStyleForKey()** can be used to determine which style is in effect at a given time. This API should be used instead of relying on #ifdef WIN32 so that your drawing will be correct in all cases. For instance, InterfaceBuilder lets the user specify what interface style to show when editing nibs so that you can see what your interface will look like on any supported platform without actually having to be running on that platform.

The default **NSInterfaceStyle** can be used to control what style to use. By default the native interface style will be used, but you can override that with this default. Currently supported values are **Windows95** and **Mach**. Not everything can obey this setting, but most AppKit objects do.

NSPopUpButton

NSPopUpButtons no longer have NSButtonCells for items, the items in a popup now have the type **(id <NSMenuItem>)**. Also, The **-(NSMatrix *)itemMatrix** method has been replaced with **-(NSArray *)itemArray** which returns an NSArray instead of an NSMatrix.

NSButton and NSButtonCell

The **setType:** method in NSButton and NSButtonCell has been renamed to **setButtonType:**, because the old name overloaded a method inherited from NSCell.

NSMatrix

Two new convenience methods have been added to NSMatrix:

```
- (int)numberOfRows;
- (int)numberOfColumns;
```

NSSavePanel

NSSavePanel now inherits from NSObject in the OpenStep specification to gain greater portability. This means that although on Mach NSSavePanel is implemented as a subclass of NSPanel, methods inherited from NSPanel and NSWindow are not considered part of the spec. In fact, on Windows NSSavePanel is implemented as subclass of NSObject since we are using the native UI.

A new method has been added to the SavePanel to validate the visible columns. For instance, say your filtering criteria have changed. Call this method to get the correct files displayed:

```
- (void)validateVisibleColumns;
```

NSScrollView

Methods have been added to access the content view of the ScrollView. The content view is the scroll view's clip view:

```
- (void)setContentView:(NSClipView *)contentView;
- (NSClipView *)contentView;
```

Windows application lifetime issues

Applications under Windows introduce some interesting life cycle issues. One issue is that because the menus are only present inside of windows, an application with no open windows has no UI. Another issue is that when you double-click a file, Windows generally starts a fresh copy of the associated application to open it even if there's another copy already running. In OPENSTEP we have addressed these issues by defining some default behaviors and providing some new API to ensure that developers can control the behaviors if necessary.

By default, on Windows, an Application will terminate when the last menu-bearing window is closed. In general, this is the right thing to do. Sometimes, however, you may need to do something different. A new NSApplication delegate message has been added to allow you to override this default behavior. When NSApplication notices the last menu-bearing window has been closed, it will send **-(BOOL)applicationShouldTerminateAfterLastWindowClosed:(NSApplication *)sender** to the application's delegate if it responds. This message is sent on both Mach and Windows so it may be necessary to tailor your app's response for the platform. On Mach, application do not, by default, terminate when windows are closed. If you implement this method you should return YES if the application should terminate and NO if it should not. If you return YES you will shortly receive an -applicationShouldTerminate: messageas well. If you return NO you should also have arranged for some UI to remain. If you return NO and do nothing else, you are likely to lose all UI to your app and leave the user with no way to quit or do anything else.

On the other end of the life cycle, a new Windows-only feature has been added to NSApplication. If the arguments to the application on the command line includes the argument pair "-NSUseRunningCopy YES" then the app will check to see if a copy of itself is already running, and if it is, it will hand off to the running copy and exit. Any -NSOpen or -NSPrint requests will be forwarded on to the existing copy. When file associations are made for OpenStep apps, these arguments are included in the association. Therefore, double-clicking multiple .draw documents should end up opening them in a single copy of Draw. This feature is supported through a single NSApplication method. + **(void)useRunningCopyOfApplication** is called from the default implementation of the WinMain function. Apps that never want to use this feature can implement their own WinMain and avoid calling this method, but there should be very few good reasons to want to do that.

NSPasteboard and the NSFileContentsPboardType

NSFileContentsPboardType has been modified slightly to be the same as NSFileWrapper's serializedRepresentation. We expect this change to make the type much more useful. Among other things this means that NSFileContentsPboardType and NSRTFDPboardType use identical formats. There is still a semantic difference between the two, however. NSRTFDPboardType is used only for

RTFD text and it must satisfy certain constraints on the actual file contents written (eg there must be a file inside called TXT.rtf and so forth).

In support of this change, and to make it easier to use NSFileContentsPboardType in your applications, NSPasteboard has some new API for dealing with this type. In the past you had to write this type onto the pasteboard from the filesystem. And when you read it from the pasteboard you had to write it to the file system. Now it is possible to wirte this type from an NSFileWrapper instance and to read it out and get a new NSFileWrapper instance. The disk need not be involved anymore. The new API is:

```
- (BOOL)writeFileWrapper:(NSFileWrapper *)wrapper;
- (NSFileWrapper *)readFileWrapper;
```

Notification name changes

Some of the names of AppKit notifications have changed to follow the general naming guidelines.

Old Name	New Name
NSColorListChangedNotification	NSColorListDidChangeNotification
NSColorPanelColorChangedNotification	NSColorPanelColorDidChangeNotification
NSImageRepRegistryChangedNotification	NSImageRepRegistryDidChangeNotification
NSViewFocusChangedNotification	NSViewFocusDidChangeNotification
NSViewFrameChangedNotification	NSViewFrameDidChangeNotification
NSViewBoundsChangedNotification	NSViewBoundsDidChangeNotification

NSDragOperation removed

The **NSDragOperation** typedef has been removed from the API, and all uses are replaced by **unsigned int**, since the values used for this type must be often or'ed together.

NSPageLayout

NSPageLayout now inherits from NSObject in the OpenStep specification to gain greater portability. This means that although on Mach NSPageLayout is implemented as a subclass of NSPanel, methods inherited from NSPanel and NSWindow are not considered part of the spec. In fact, on Windows NSPageLayout is implemented as subclass of NSObject since we are using the native UI.

In addition, the following methods and types have been removed from the OpenStep specification, but are still available on the Mach platform:

```
- (void)convertOldFactor:(float *)old newFactor:(float *)new
- (void)pickedButton:(id)sender.
- (void)pickedOrientation:(id)sender
- (void)pickedPaperSize:(id)sender
- (void)pickedUnits:(id)sender

enum {
NSPLImageButton, NSPLTitleField,
NSPLPaperNameButton,
NSPLUnitsButton,
NSPLWidthForm,
NSPLHeightForm,
NSPLOrientationMatrix,
NSPLCancelButton,
NSPLOKButton
};
```

The **runModal** and **runModalWithPrintInfo:** methods now return NSOKButton or NSCancelButton on all platforms.

NSPrintInfo

There are two new keys available in the NSPrintInfo dictionary on the Windows platform:

```
NSPrintMustCollate
```

NSPrintFormName

NSPrintMustCollate indicates whether collation occurs when multiple copies are printed. NSPrintFormName is the form name associated with the current print request, which might be different from the NSPrintPaperName.

NSPrinter

A new method has been added to return the names of configured printers available to the system. This name can then be passed to **printerWithName:** to create an NSPrinter. If no printers are available, an empty array is returned. If an error occurs, nil is returned.

```
+ (NSArray *)printerNames
```

NSPrintPanel

The NSPrintPanel class has been removed from the OpenStep specification. In addition, these related methods in NSPrintOperation have been removed from the specification :

```
- (void)setPrintPanel:(NSPrintPanel *)panel;
- (NSPrintPanel *)printPanel;
```

NSPrintPanel is still available as a platform specific interface; however, it now inherits from NSObject rather than NSPanel.

NSPrintOperation

The following methods were added to NSPrintOperation in the OpenStep specification to allow the accessory view to be set in the print panel:

```
- (void)setAccessoryView:(NSView *)aView;
- (NSView *)accessoryView;
```

The following methods have also been added to the specification. These methods are sent to the accessory view passed to the above methods if it responds to them.

```
- (void)updateFromPrintInfo;
- (void)finalWritePrintInfo;
```

New Graphics functions

Four new functions have been added to support conformance to the Windows UI look:

```
void NSRectFillListWithColors(const NSRect *rects, NSColor *colors, int count);
```

Fills each rectangle in the array *rects* with the color whose value is stored at the corresponding location in the array *colors*. Both arrays must be count elements long. Avoid rectangles that overlap, because the order in which they'll be filled can't be guaranteed.

```
void NSDrawDarkBezel(NSRect aRect, NSRect clipRect)
```
Draws a bordered rectangle with the appearance of a pushed-in button, clipped by intersecting with clipRect.

```
NSRect NSDrawColorTiledRects(NSRect boundsRect, NSRect clipRect, const NSRectEdge *sides,
NSColor *colors, int count)
```

Draws an unfilled rectangle, clipped by *clipRect*, whose border is defined by the parallel arrays *sides* and *colors*, both of length *count*. Each element of *sides* specifies an edge of the rectangle, which is drawn with a width of 1.0 using the corresponding color from *colors*. If the *edges* array contains recurrences of the same edge, each is inset within the previous edge.

```
void NSDrawLightBezel(NSRect aRect, NSRect clipRect)
```

Draws a rectangle with the appearance of an editable text field. Only the area that intersects *clipRect* is drawn.

NSFont

The method **maximumAdvancement** was added to the API to return the advancement of the widest glyph in the given font. If the font is fixed-pitch, this is the advancement of all the glyphs.

The following API additions (which are not in OPENSTEP) allow one to get/set a list of the user's "preferred" fonts, which are checked (in order) before any other fonts when searching for a font to render some character that cannot be rendered in a pre-given or specified font. The list should typically contain fonts with different encodings and glyph complements, as available.

```
+ (NSArray *)preferredFontNames;
+ (void)setPreferredFontNames:(NSArray *)array;
```

API has also been added to access the Windows system fonts.

```
+ (NSFont *)menuFontOfSize:(float)fontSize;
+ (NSFont *)titleBarFontOfSize:(float)fontSize;
+ (NSFont *)messageFontOfSize:(float)fontSize;
+ (NSFont *)paletteFontOfSize:(float)fontSize;
+ (NSFont *)toolTipsFontOfSize:(float)fontSize;
```

The existing NSFont methods systemFontOfSize: and boldSystemFontOfSize: now return the same as messageFontOfSize: and titleBarFontOfSize: respectively. This API is valid on Mach and Windows. On Mach it returns the standard system or bold system fonts. On WIndows it will return the user's font settings from the Display options control panel if the user's chosen fonts can be supported (currently bitmap fonts are not supported, but TrueType fonts are).

NSFontManager

NSFixedPitchFontMask mask was added so that the font manager can determine whether or not a font is fixed-pitch. It may be used in trait queries.

The method **fontNamed:hasTraits:** was added to help in searching for fonts with specified traits. The available traits are specified by the trait masks.

The new method **availableFontNamesWithTraits:** uses the given mask (which may contain several one bits) in testing the available fonts. The names of all fonts matching the given bits are returned in an array.

NSInputManager/NSInputServer

The method **doCommandByName:** was removed from the API and from the NSTextInput protocol in favor of **doCommandBySelector:**. (The latter was already in the API, but has been added to the NSTextInput protocol.) Along the same lines the NSInputServer method **doCommandByName:sender:conversation:** was also obsoleted.

The method **localizedInputManagerName** replaces the method **inputManagerName**.

Dead Keys

Dead key handling in DPSClient is now off by default. The new text object and keyboard UI rely on the input management layer to simulate dead keys. NSCStringText will turn dead key handling on and off as it gains and loses first responder status. Other custom views which need dead keys to be handled by DPSClient should also use the same approach.

Help System

The AppKit's Help API has changed significantly. NSHelpPanel has been obsoleted in favor of a new class, NSHelpManager. NSHelpManager provides a more platform-independent approach to presenting help.

Previously, the only way for your application to present help was through the NEXTSTEP Help panel. Context-sensitive help and all other help for your application was displayed in the Help panel. This made sense when NEXTSTEP was the only platform for your application.

OpenStep applications, however, can run on multiple platforms, and each platform provides its own support for online help. It's important to users that applications use the native online help system (on Windows, for instance, users want the Windows help system and don't want to have to learn how to use a different help system), so NSHelpManager does not provide a comprehensive solution for presenting help. Instead, it provides cross-platform support for context-sensitive help, and allows you to present more comprehensive help (conceptual and task-based help) in any way you choose.

Context Help

Context-sensitive help (also referred to as context help) gives the user a small amount of information when they help-click on an interface item. For example, if the user help-clicks on a menu item called "Copy", they should get context help that says something like "Copies the currently selected text to the pasteboard." This text appears in a small window near where the user help-clicked, and the window disappears when the user clicks anywhere else in the application.

To provide context help for your application, follow these steps:

1. For each interface item that needs context help, create an .rtf or .rtfd file containing the text and any images you want to appear when the user help-clicks on that interface item. Try to keep the text as brief as possible and the images as small as possible.

2. If you don't need to localize your context help files, in Project Builder simply add these files to the Context Help suitcase of your project.

If you do need to localize your context help files, first copy the files into the appropriate **.lproj** directory of your project, then use Project Builder to add them to the Context Help suitcase of your project.

3. In Interface Builder, connect each interface item to its context help file by doing the following:
a. Bring up the Interface Builder inspector and choose the Help display. The Help display lists all the context help files associated with your application.
b. Select an interface item.
c. In the inspector, choose the appropriate help file.

When you compile your application, **/usr/bin/compileHelp** packages your help files into a property list named Help.plist. NSHelpManager knows how to extract context help from an Help.plist file.

Comprehensive Help

Most applications provide some form of online help that is more comprehensive and detailed than context-sensitive help, such as conceptual or task help. NSHelpManager allows you to provide this sort of comprehensive help in any way you choose. Some help authors prefer to provide comprehensive help in HTML using a World-Wide Web browser; others use tools such as Digital Librarian or Concurrence; on Windows a full-featured native help system is available. Given the availability of rich tools like Digital Librarian and HTML browsers, OpenStep on Mach no longer supplies a native help system for comprehensive help.

When the user chooses the Help menu item, NSHelpManager simply asks the Workspace Manager to

open the help file you have specified for your application. That file should be the starting point of your help, and should allow users to access whatever information they might need.

To specify a help file for your application, do one of the following:

· The simplest approach, not requiring you to specify the help file anywhere in your application, is to place the help file in your app wrapper and name it after your application. If you haven't specified a help file, NSHelpManager looks in the app wrapper for an appropriately named file.

On Mach, it must be an rtf file called <appName>.rtf.

On Windows, it must be a Windows help file called <appName>.hlp.

· To specify a help file that applies to all platforms, define the NSHelpFile key in your project's CustomInfo.plist file:

```
{
NSHelpFile = "ApplicationHelp.rtfd";
}
```

If your project does not have a CustomInfo.plist, simply create one (as in the example), and add it to your project's "Supporting Files" file category. When you build your project, the contents of CustomInfo.plist will be merged into your application's Info.plist

The specified value for the NSHelpFile key can be a full or relative path, and if it is relative, it is assummed to be a bundle resource (resolved using [[NSBundle mainBundle] pathForResource: <NSHelpFile value> ofType:nil]).

pswrap - new flags

pswrap supports some new flags which you may need to use in various circumstances.

-H <dir> This flag tells pswrap where to look for the dpsfriends.h file which needs to be included in the generated source. Passing '-H AppKit' will pick up the file from the OPENSTEP AppKit.
-I <include> This flag tells pswrap to emit an extra import statement. This flag in conjunction with the -e flag described below can be used by framework developers who need to export pswraps from their frameworks on Windows. Passing '-I \\"MyFrameworkDefines.h\\"' will cause '#import "MyFrameworkDefines.h"' to the generated source.
-e <extern decl> This flag tells pswrap how to declare extern functions in the generated headers. If your pswraps need to be exported from a framework project, you will need to supply an appropriate declaration for exporting the functions. Passing '-e MYFRAMEWORK_EXTERN' will cause "MYFRAMEWORK_EXTERN" to be used instead of "extern" when declaring external function prototypes.

The AppKit exports many pswraps. In order for those wraps to be truly exported on Windows, the AppKit has something like this in its Makefile.preamble:

PSWFLAGS = -I \\"AppKitDefines.h\\" -e APPKIT_EXTERN

Look at the AppKitDefines.h header file in $NEXT_ROOT/NextLibrary/Frameworks/AppKit.framework/Headers to see how this works. All Framework projects that have any functions in them should have a similar header file with a similar macro. Just remember to add these flags to pswrap if you need to export the wraps from your framework.

Localization

There are several localization features that are not documented elsewhere:

· It's possible to change the order of the arguments in a localized string by using the "$" modifier and the argument number:

```
/* Message in alert panel when something fails */
"Oh %@! %@ failed!" = "%2$@ blah blah, %1$@ oh!";
```

· The default **NSShowNonLocalizableStrings** can be used to catch strings which are not localizable. The strings will be logged and also displayed in the UI in upper case. Note that there will be some false positives, but this is still useful.

· The default **NSShowNonLocalizedStrings** will indicate strings which were meant to be localized but could not be found in the strings files. This can be used to catch problems with out-of-date localizations.

OPENSTEP 4.2: Foundation Framework Release Notes

The Foundation Framework is a library of Objective-C classes providing the infrastructure for non-user-interface object-based applications and other user-interface- and non-user-interface-based frameworks. The OPENSTEP Foundation is compliant with the Foundation portion of the OpenStep specification, and enriches OpenStep with a few extensions.

Within the Foundation are basic classes used by any Objective-C program: collection classes, Distributed Objects, persistence frameworks, Unicode and internationalization support, the foundations of event-driven programming, and facilities to insulate code from the underlying operating system.

These release notes are divided in three main sections:

- Comments on compatibility with OPENSTEP 4.0 and 4.1
- General comments on often-encountered issue areas and interesting things
- Known issues in this release

In the document below, "4.0" and "OPENSTEP 4.0" refer to all products that shipped with the 4.0 Foundation: OPENSTEP 4.0, D'OLE 4.0, and PDO 4.0 for HP-UXTM and SolarisTM. "4.1" and "OPENSTEP 4.1" refer to OPENSTEP 4.1 for Mach and OPENSTEP Enterprise 4.1. "4.2" and "OPENSTEP 4.2" refer to OPENSTEP 4.2 for Mach and OPENSTEP Enterprise 4.2. All trademarks are property of their respective owners.
This article has been archived and is no longer updated by Apple.

Changes and Compatibility Between OPENSTEP 4.0, 4.1, and 4.2

There have been a number of changes to Foundation since the shipment of OPENSTEP 4.0 and a few since 4.1, both defect fixes and a few API additions. These are enumerated in the section below.

Note that if your application uses API which was added after 4.0, your application might not run under 4.0 (and similarly with 4.1 and API added after 4.1). (If you do not want to deploy your application on 4.0 or 4.1, then this is not an issue.) You can catch some of the potential issues by defining the macros **STRICT_40** and/or **STRICT_41** at compile time. This #define is similar to **STRICT_OPENSTEP** and is used in the Application and Foundation Frameworks to mark new API. Similarly, if you rely (perhaps unintentionally) on a bug fixed in 4.2, your application may not function correctly under 4.0 or 4.1. Make sure you test on your intended deployment platform.

A number of performance improvements have also made to Foundation for each release. Customers developing on 4.2 may find performance to be significantly worse in some cases when an application is deployed on 4.0, for example.

Here are the feature changes to Foundation in 4.1 (from 4.0):

Some methods in 4.0 were not surrounded by `#if !defined(STRICT_OPENSTEP)` when they weren't, in fact, in OpenStep.

CLASS	HEADER	METHOD
NSCharacterSet	NSCharacterSet.h	+characterSetWithContentsOfFile:
NSConnection	NSConnection.h	-connection:shouldMakeNewConnection:
NSArray	NSPathUtilities.h	-pathsMatchingExtensions:

These methods were made public in 4.1. They were not public in 4.0, but existed in the 4.0 Foundation binary so there are no compatibility issues in using them. They are not in OpenStep, however.

CLASS	HEADER	METHOD
NSArray	NSArray.h	-makeObjectsPerformSelector:
NSArray	NSArray.h	-makeObjectsPerformSelector:withObject:
NSSet	NSSet.h	-makeObjectsPerformSelector:
NSSet	NSSet.h	-makeObjectsPerformSelector:withObject:

These methods and functions were added to Foundation in 4.1 and are not present in the 4.0 Foundation binary. Applications which do not take some precaution in using them will not run correctly on OPENSTEP 4.0. These methods and functions are also not in OpenStep.

CLASS	HEADER	METHOD
NSBundle	NSBundle.h	+allBundles

NSBundle	NSBundle.h	+allFrameworks
NSFileHandle	NSFileHandle.h	+fileHandleWithNullDevice
NSFileHandle	NSFileHandle.h	-initWithNativeHandle:closeOnDealloc:
NSFileHandle	NSFileHandle.h	-initWithFileDescriptor:closeOnDealloc:
NSObject	NSObject.h	+instanceMethodSignatureForSelector:

FUNCTION	HEADER
NSFrameAddress	NSDebug.h
NSReturnAddress	NSDebug.h
NSCountFrames	NSDebug.h

Here are the feature changes to Foundation in 4.2 (from 4.1):

Some methods in 4.1 were not surrounded by #if !defined(STRICT_OPENSTEP) when they weren't, in fact, in OpenStep. They were guarded with #if !defined(STRICT_40).

CLASS	HEADER	METHOD
NSBundle	NSBundle.h	+allBundles
NSBundle	NSBundle.h	+allFrameworks
NSObject	NSObject.h	+instanceMethodSignatureForSelector:

This method was made public in 4.2. It was not public in 4.0 or 4.1, but existed in the 4.0 and 4.1 Foundation binaries so there is no compatibility issues in using it. It is not in OpenStep, however.

CLASS	HEADER	METHOD
NSDictionary	NSDictionary.h	-initWithDictionary:copyItems:

This method was made public in 4.2. It was not public in 4.1, but existed in the 4.1 Foundation binary so there is no compatibility issues in using it for 4.1 deployment. It does not exist in the 4.0 binary. It is also not in OpenStep.

CLASS	HEADER	METHOD
NSBundle	NSBundle.h	-load

These global variables were added to Foundation in 4.2 and are not present in the 4.0 nor the 4.1 Foundation binaries. Applications which use these global variables will not run on OPENSTEP 4.0 or 4.1. These global variables are not in OpenStep.

VARIABLE	HEADER
NSFileHandleDataAvailableNotification	NSFileHandle.h
NSPositiveCurrencyFormatString	NSUserDefaults.h
NSNegativeCurrencyFormatString	NSUserDefaults.h

These methods were added to Foundation in 4.2 and are not present in the 4.0 nor the 4.1 Foundation binaries. Applications which do not take some precaution in using them will not run correctly on OPENSTEP 4.0 or 4.1. These methods are not in OpenStep.

CLASS	HEADER	METHOD
NSFileHandle	NSFileHandle.h	-waitForDataInBackgroundAndNotifyForModes:
NSFileHandle	NSFileHandle.h	-waitForDataInBackgroundAndNotify
NSRunLoop	NSRunLoop.h	-configureAsServer
NSTask	NSTask.h	-interrupt

Some API was added to NSDebug.h. Production programs should not be referring to symbols declared in NSDebug.h.

General Comments

NSDates and the Year 2000

Dates are represented in Foundation with NSDate (and NSCalendarDate) objects and NSTimeInterval values. An NSTimeInterval is essentially a C-language double. NSDates (and NSCalendarDates) store the date that they represent with an NSTimeInterval, which represents the time delta, in seconds, from the Foundation reference date, 00:00:00 1 January 2001 GMT. This time delta is negative until the reference date. There is no special significance to the year 2000 to NSDate objects or NSTimeInterval values. However, refer to the topic *Risks in Parsing and Displaying Dates* in this section for more information on issues in date presentation and the year 2000.

Since the internal time representation will transition across zero (at the reference date) at some point in the future, unlike some other schemes which set the epoch to a date "always" in the past, there will be a brief instant, on the order of microseconds in length, in which an NSDate object created to represent the current time will have an NSTimeInterval of 0.0. The length of this instant is dependent on the resolution of the system time provided by the particular operating system and platform an application is running on. An NSTimeInterval of 0.0 has no special significance to NSDate or NSCalendarDate, but applications which use the NSTimeInterval of a date object in division should protect against division by zero. Such applications are vanishingly rare. More common might be to have an NSTimeInterval which represents the delta between two arbitrary date objects (such as when timing events), and applications should take appropriate caution in using such values (this is always a good idea apart from date usage).

Risks in Parsing and Displaying Dates

As with any communication between a program and a user, there can be miscommunication in showing dates to the user and reading dates the user types in. When a user types a date into a text field in an application they may intend one thing, and the program may interpret the date as something else. When a date is displayed to a user, the user may interpret the date incorrectly. While an application cannot control the user, there are certain things that an application can avoid doing, with respect to dates, to reduce the potential for confusion and ambiguity and data corruption.

- Avoid two-digit years and all uses of the "%y" date format specifier.
- Do not use natural language date parsing.
- Avoid time zone abbreviations.

Each of these points is explained in greater detail below. Whenever it is important (or critical) that the user get accurate information from the application, or the application get accurate information from the user, an application should avoid the ambiguous behaviors below and require strict conformance to a fully specified input format (for user input) and provide an equally verbose output description of dates. Alternatively an application could ask for confirmation of input dates, but this seems to be rather more heavyweight.

Avoid two-digit years and all uses of the "%y" date format specifier. Per POSIX and ANSI C (refer to section 7.12, ANSI/ISO 9899-1990 for ANSI C definitions), a two-digit year YY means 1900 + YY. The Foundation follows the lead of ANSI C here. Thus, when a user types "5/10/02" in to a text field with a date formatter with format "%d/%m/%y", a date of 5 October 1902 is successfully created. If the user meant 5 October 2002, they haven't entered that. Since %y means "two-digit year" it is not possible for the user to type anything that will get them a date in the year 2002 (for example, if the user types "5/10/2002" in this example, a date of 5 October 1920 will be successfully parsed). The date parsing routines parse at most two-digits for %y, in order to support dates formatted like "980409" (also not a good idea). Conversely, a user has no way of knowing whether "28/10/33" refers to 1933 or 2033 if they see that displayed on the screen or in printed output. If a program uses "%Y" in the format string instead, this issue is avoided.

Do not use natural language date parsing. The natural language parser is pretty sophisticated, but it is after all just sophisticated guessing. The natural language parser is also usually successful at creating a date from input, as long as the input is moderately close to something that looks like a date. However, as with the previous issue, this may not be the date the user intended. Relatedly, don't enable natural language parsing for date formatters. If it is enabled, and the user's input does not match the date formatter's format, the input string is given to the natural language parser.

Here is an example where the natural language parser may fail to parse the date the user intended: suppose the date formatter has a format "%d/%m/%Y" and the user types in "5-10-2002". This does not match the format (which has slashes), so the date formatter gives the input to the natural language parser. Now, what the "5" means and what the "10" means is ambiguous±it could equally be month-day-year or day-month-year. The natural language parser prefers a particular ordering, given by the NSDateTimeOrdering preference. If the user's preferred language is French, this is DMYH (denoting an ordering: day month year hour). The built-in default, if the user has no preferred language, is MDYH (denoting an ordering: month day year hour). NSDateTimeOrdering could also be set explicitly to something else by the user. If the user's preferred language is French, the date will be "correctly" parsed as 5 October 2002. By default it will be parsed as 10 May 2002. In general, an application writer can't know a priori what the preferences of the user will be. If natural language parsing is desired, this and other issues (such as use of 12- or 24-hour hour designations) should be taken into account and dealt with by the application.

Avoid time zone abbreviations. Time zone abbreviations are inherently ambiguous. Many time zones around the world map to the same abbreviations, by local convention, and there is usually very little information in the abbreviations (most are of acronyms of a phrase such as "*Something* Standard Time" or "*Something* Daylight Time", where the *Something* is the only differentiator). A time of 11:00 CST means something different to a person in New York, New York, U.S.A. (indicating time in Chicago) than someone in Sydney, Australia (indicating time in Darwin) (that hour by itself is also ambiguous; is it *ante meridiem* or *post meridiem*?). Use of time zone names of the form GMT+hhmm and GMT-hhmm (as in GMT+0100) can also be problematic, since the user cannot know what which convention (simple offset, or the POSIX minutes-west) is being used. Thus, GMT+0200 can indicate either Helsinki or the mid-Atlantic.

Foundation's Time Zone Data

The Foundation now uses its own time zone data files (which describe when changes to the standard time zone corrections from GMT occur) on all platforms. This provides for greater consistency of behavior, and the ability to unarchive and transport time zones to any Foundation platform. However, it's possible that the time zone data may become out-of-date relative to a particular platform's data as, for example, new operating system updates are installed, but the new versions of PDO or OPENSTEP are not. The Foundation's time zone data comes from a freely available source at elsie.nci.nih.gov, and is current with that source as of November, 1996. The Resources/TimeZoneInfo directory inside the Foundation.framework contains a file README.TimeZoneInfo which explains how the time zone data for Foundation can be updated from this source, if required. Part of the reason for choosing the data from elsie.nci.nih.gov is that it is an easily accessible source of current information (it is updated about once per month). It is also quite complete.

The time zone data that Foundation uses in 4.2 is compatible with the data used in 4.0 and 4.1. However, to save disk space on machines with disks with large allocation-block sizes, all of the data is bundled up into a serialized property list (TimeZones.splist). The top-level property list is a dictionary where the keys are time zone names (the same as the file names in 4.1) and the values are NSData objects containing the bytes of the files. To use the data to update a 4.1 installation (for example), the data objects in this file would need to be extracted into files with the file names given by the keys. It is fairly straightforward to write a Foundation-based program to do this. An example of the opposite process, taking a directory hierarchy and making the serialized property list is given in the Resources/TimeZoneInfo/README.TimeZoneInfo file described above.

With the adoption of the time zone data from elsie.nci.nih.gov, Foundation has also adopted the zone naming conventions of that data, where zone names usually have the form Area/Location, as in America/Sao_Paulo or Europe/Paris. The previous, and conventional UNIX, time zone names are supported for backwards compatibility.

The set of time zone abbreviations has also changed somewhat. How abbreviations map to time zones is an arbitrary choice of the Foundation, since time zone abbreviations are ambiguous. Use of time zone abbreviations is not encouraged (see Risks in Parsing and Displaying Dates in this section for more information). Sites can customize this to some extent±see the file Resources/TimeZoneInfo/README.TimeZoneInfo in the Foundation.framework.

Using performSelector: with Selectors Which Don't Return `id'

The NSObject methods -performSelector:, -performSelector:withObject:, and -performSelector:withObject:withObject: have an "id" return value. This is something of a holdover from pre-4.0 conventions where methods without otherwise interesting return values returned self. Much of the time one can "get away with" performing a selector to an object with these methods, where the target method does not have a return value or has a non-object return value. Such use is semantically suspect, however, and is not valid. Any situation where the -performSelector:... message may be forwarded will quickly illustrate this (with an abnormal program termination), as the NSInvocation object attempts to retain the return value from after invocation, because the selector for -performSelector:... is typed to return an object. Sending -performSelector: to a faulted object with a selector that does not return id is an example of this. This behavior extends also to various other "perform" methods such as the -makeObjectsPerformSelector: of some collection classes and the "delayed perform" and "ordered perform" methods in NSRunLoop.h.

Where Do NSLog()'d Messages Go?

NSLog() and NSLogv() do not log an error message to stderr, as stated in the documentation.

On HP-UX, Solaris, and Mach, it writes the log to STDERR_FILENO if the file descriptor is open. If that fails, the message is sent to the syslog subsystem, if it exists on a platform, with the LOG_USER facility (or default facility if LOG_USER doesn't exist on a platform), with priority LOG_ERR (or similar, depending on what the platform supports). If both of these attempts to write the message fail, the message is discarded.

On Windows platforms, the message is written to the STD_ERROR_HANDLE, if that handle is valid, on Windows platforms that support that standard handle. It is also written to the Windows Event Log on Windows platforms that support the Event Log, or to the file c:\\fndation.log on Windows platforms that do not, if that file can be opened. If all of these attempts fail, the message is discarded. On some Windows platforms, the message to the Event Log may be truncated if there is a limit to the size of a message that the Event Log can accept. On Windows platforms that support an application discovering whether or not it is running under a debugger, NSLog() and NSLogv() may only send the message to the debugger for its handling, via standard WIN32 mechanisms, and not also write the message to STD_ERROR_HANDLE and the Event Log. Note that a debugger may choose to not display messages thus sent to it, or may choose not to display all of the message±NSLog() and NSLogv() have no control over that.

Output from NSLog() and NSLogv() is serialized, in that only one thread in a process can be doing the writing/logging described above at a time. All attempts at writing/logging a message complete before the next thread can begin its attempts.

The effects of NSLog() and NSLogv() are not serialized with other subsystems than those discussed above (such as the standard I/O package) and do not produce side effects on those subsystems (such as causing buffered output to be flushed, which may be undesirable).

The format specification allowed by NSLog() and NSLogv() is that which is understood by NSString's formatting capabilities. That is not necessarily the set of format escapes and flags understood by printf(), as mentioned in the documentation.

Foundation Examples

There are several Foundation examples in /NextDeveloper/Examples/Foundation.

I/O Functionality

Two Foundation classes, NSFileHandle and NSPipe, provide objects that represent open files or communications channels and support basic I/O operations. They make it easy for developers to write code that is directly portable to other platforms. The interfaces for these classes are declared in NSFileHandle.h. These classes replace the NSPosixFileDescriptor and NSPosixPipeDescriptor classes made available in OPENSTEP 4.0 prereleases. The differences from the predecessor classes for the most part involve naming and a refinement of semantics.

Note that the new (in 4.2) -waitForDataInBackgroundAndNotify functionality only works for NSFileHandles which refer to sockets.

Archiving

NSUnarchivers own the objects that they decode. When an NSUnarchiver is deallocated, so are the objects that it has decoded, unless they have been retained. The following code, for example, will probably result in a decoded object being used after being freed:

```
NSAutoreleasePool *pool = [[NSAutoreleasePool allocWithZone:NULL] init];
NSUnarchiver *unarchiver = [[NSUnarchiver allocWithZone:NULL] initForReadingWithData:myData];
id object = [unarchiver decodeObject];
[unarchiver release];
[pool release];
... use or return object here ...
```

object should be retained before the NSUnarchiver is released, and probably also autoreleased if object is returned from the function or method. An exception to this are the -decodeValueOfObjCType:at: and -decodeValueOfObjCTypes:... methods. Objects "returned" from these two methods, like those returned from +allocWithZone: and -copyWithZone:, are not autoreleased, and must be explicitly released.

User Defaults

Foundation contains API (NSUserDefaults) which replaces the old defaults database suite of functions. User defaults with 4.0 applications are stored differently and in a different place than 3.3 user defaults. There is a new command-line utility called defaults that allows you to manipulate the new-style defaults just as dread, dwrite, and dremove allowed you to manipulate old-style defaults.

On Windows NT, defaults are stored in the Windows registry. There is a program shipped with Windows NT, REGEDT32, for viewing and editing registry entries. NSUserDefaults stores its domains and their key-value pairs under the entry HKEY_CURRENT_USER\\Software\\NeXT\\UserDefaults. The values are currently stored as strings in the property list format.

The command /usr/bin/defconvert, in OPENSTEP 4.x for MACH, can be used to convert a user's 3.3 defaults database to 4.x-style defaults--simply run it from the command line with no parameters. This program converts all old-style defaults, even those of non-OpenStep applications, adding them to the user's new-style database. Since NEXTSTEP 3.3 applications may not use the same default names after conversion to OPENSTEP 4.x, and 3.3 applications do not use the new defaults database, and increasing the size of the defaults database increases the amount of memory needed by each OpenStep application, converting an old defaults database to the new style usually provides little utility.

Errors in ASCII Property Lists

When a method like NSDictionary's +dictionaryWithContentsOfFile: is used to read and parse an ASCII property list from a file, parse errors and exceptions are suppressed, and nil is returned upon error. Sometimes a program wants to know about syntax errors in a property list, or wants finer-grained information about why a property list cannot be read and parsed. Another method, NSString's -propertyList, can be used for this purpose. The following example illustrates this:

```
- (id)readPropertyListFromFile:(NSString *)path mustBeOfType:(Class)targetClass logErrors:(BOOL)showErrors {
NSString *string;
id plist = nil;
```

```
string = [[NSString allocWithZone:NULL] initWithContentsOfFile:path];
if (showErrors && nil == string) {
NSLog(@"%@: string could not be read from '%@'", NSStringFromSelector(_cmd), path);
}
NS_DURING
plist = [string propertyList];
NS_HANDLER
if (showErrors) {
NSLog(@"%@: received exception while parsing: %@", NSStringFromSelector(_cmd), localException);
}
plist = nil;
NS_ENDHANDLER
[string release];
if (Nil != targetClass && ![plist isKindOfClass:targetClass]) {
if (showErrors) {
NSLog(@"%@: property list is not of desired type '%@'. It's an '%@'.",
NSStringFromSelector(_cmd), NSStringFromClass(targetClass), NSStringFromClass([plist class]));
}
[plist release];
plist = nil;
}
return plist;
}
```

Grammars for Serialization and ASCII Property List Formats

Grammars and description of the serialization (NSSerializer) and ASCII property list representation formats are available in the appendix to the OpenStep specification.

Strings which contain non-alphanumeric characters must be double quoted in property lists to ensure the entire string is parsed as one string object. Parse failures will result, otherwise.

Retain Cycles and Invalidation

The retain/release strategy used in Foundation allows an incautious programmer to create reference cycles in an object graph (that is, the graph of objects that retain one another in some manner). These cycles are self-sustaining and constitute a memory leak. The simplest example is to create a NSMutableArray instance and add it to itself. Since an array retains its objects, it retains itself independent of its normal usage. Retains are essentially distributed across the network via the Distributed Objects mechanism.

If retain cycles cannot be avoided by careful design, but are known a priori, the following technique can be used to recover the memory. For the objects in the cycle(s) whose retain counts are solely due to the cycle, all should be retained (perhaps in an array), each one told to release its retained objects, then all released. The action of releasing its retained objects would undoubtedly cause an object to become dysfunctional. Some objects already implement such a method by the name "-invalidate". It is a bug that neither NSObject nor the collections implement this method to facilitate cycle recovery.

More on Autoreleasing and Retaining

The following statements are false:

Returned objects are guaranteed to be valid for the scope of the current method.

Returned objects are guaranteed to be valid until the current autorelease pool is released.

Returned objects are guaranteed to be valid until the end of the current event loop.

The Foundation's retain count mechanism operates via -retain and -release. A code fragment such as:

```
id object = [collection returnObject];
```

creates a reference (in object) to the returned object, but does not increment the retain count of object. If you don't let the system know about your reference, by incrementing the retain count with -retain, the system can't ensure that your reference remains valid for any length of time. For example:

```
object = [array objectAtIndex:7]; // get object
[array removeObjectAtIndex:7]; // removes object and releases it
[object dosomething]; // object may be invalid here
```

- In that example, if array had the last retain on object, the second line will cause object to be deallocated and the third line will cause the application to crash. Here is another example with the AppKit:

```
id oldTitle = [myWindow title]; // get current title
[myWindow setTitle:@"Calculating..."]; // set temporary title
... do calculation here ...
[myWindow setTitle:oldTitle]; // restore previous title
```

Here, the -setTitle: method gets rid of its reference to the existing title string and takes a reference to the new title string. If the window had the only reference to the previous title string object, the last line of the example will attempt to setTitle: to a freed object. If the AppKit in its implementation happens to send -autorelease to the old title instead of -release, then the object referenced in oldTitle may not by freed by the time of the last line, but in general you cannot know whether such a method will release or autorelease the previous object. The Foundation almost exclusively uses -release, since that does not have the performance overhead of autoreleasing, and Foundation objects are so common in applications.

In practice, you can get away with such "weak references" much of the time. But the safest approach formalizes your reference to the object:

```
id object = [[collection returnObject] retain];
... do operations, some of which may be on object ...
/* Don't need object any longer */
[object release];
object = nil;
```

The -hash and -isEqual: Invariant

It is worthwhile to highlight an obscure requirement documented in NSObject class specification for the -hash method: The -hash and -isEqual: methods of a class must be defined so that if two objects are equal, their hash value is the same ([x isEqual:y] implies [x hash] == [y hash], but not the converse). This is easy to forget, but especially important to ensure when putting custom objects into some collections (such as NSSet and NSDictionary).

Forwarding Messages in OpenStep

Objects wishing to forward messages with the -forwardInvocation: method must also (re)implement the -methodSignatureForSelector: method. This is a result of the compiler not providing call stack descriptive information at each call site. Consequently, the runtime needs a source of information for how the stack frame is constructed. It needs this to build the invocation that will be supplied to the -forwardInvocation: method call. The -methodSignatureForSelector: method will need to be reimplemented to provide a method signature for selectors to which the object does not respond.

```
- (NSMethodSignature *)methodSignatureForSelector:(SEL)sel {
NSMethodSignature *result = [super methodSignatureForSelector:sel];

// if result is nil, self must not respond to the selector
if (nil == result)
result = [target methodSignatureForSelector:sel];
return result;
}

- (void)forwardInvocation:(NSInvocation *)invocation {
[invocation invokeWithTarget:target]; // let target implement methods that we do not
}
```

Faulted objects in EOF which wish to forward messages should also override +instanceMethodSignatureForSelector:.

See the ForwardInvocation example in /NextDeveloper/Examples/Foundation/ForwardInvocation.

Debugging Aids

The *OpenStep Conversion Guide* describes several techniques for debugging Foundation and AppKit applications. The header file NSDebug.h also has some global flags, functions, and methods which may be useful. But be warned±although this header file is public, its contents are mostly unsupported, largely undocumented, and are subject to change without warning. Do not depend on API within this header for the operation of production programs.

Object Allocation Analysis

One of the useful flags defined in NSDebug.h is NSKeepAllocationStatistics, which allows you to analyze the object allocation activity in a program. The AnalyzeAllocation command line program can be used to analyze the output generated by running with this option enabled. You can also use the ObjectAlloc demo application which comes OPENSTEP for Mach and Windows to graph the object allocation activity in real time.

The +load Method

The +load message is sent to classes when they are added to the Objective C runtime. +load is usually received before +initialize. +load is not inherited by subclasses.

The order in which +load messages are sent to classes is unspecified (and specifically, a class's superclass is not guaranteed to have its +load method called before the class receives the message). Therefore, you should not use any subsystems or classes which are loaded at the same time, or more generally, which you do not know have received the +load message. If you do, you will probably cause execution of code which assumes that +load (and anything that had to be done in +load) has been previously executed.

There are two situations typically when classes are added to the runtime:

- when loaded dynamically from a bundle or framework by NSBundle
- at application launch

The restrictions on +load are perhaps most serious at launch time. The Foundation has classes and subsystems (as might any other library) which depend on +load being called before they are fully functional. For example, you should not use NSZoneMalloc() to allocate memory in +load methods which are statically linked into an application. You certainly should not create any objects, or do anything with creates objects.

Note that calling +load on a class isn't a solution (and is a generally bad idea), because that will cause +initialize to be sent first, which the class may not handle. Not to mention that doing so places into your code dependencies on which classes implement +load in a particular version of a library. In the case of Foundation, for convenience sake, +load methods which must use Foundation API can call [NSObject self] first to make sure Foundation has performed the initialization it needs.

+load is not intended as a general initialization mechanism, and should only be used when absolutely necessary. Use +initialize for early initialization whenever possible.

Performance and NSNotificationCenter

NSNotificationCenter, although heavily optimized, by its nature can become a significant performance bottleneck if heavy use of notifications is made. The notification mechanism should be used judiciously.

NSAutoreleasePool's -addObject: Method

You should never use the NSAutoreleasePool instance method -addObject:. Use the -autorelease method, or [NSAutoreleasePool addObject:] to autorelease an object. Using the instance method incurs the risk of adding an object to a pool which is not the top autorelease pool, a semantically suspect operation, since the autorelease pool model is one of a (per-thread) stack of pools. OPENSTEP 4.x does allow you to add

objects to an autorelease pool that is not the top pool, but be warned that it is a much more expensive operation (and always will be) than adding an object to the top pool.

Frameworks as NSBundles

Frameworks are a specialized form of bundle. An application can statically link against a framework at compile time (like a library), or dynamically load a framework (like a bundle) at runtime. However, as a specialized type of bundle, there are some constraints placed on frameworks:

- A framework must have a .framework extension
- The name of the executable code of a framework must have the same name as the framework directory, minus the .framework extension. For example, the file name of the executable code for the framework MyFramework.framework must be MyFramework (or on Windows, MyFramework.dll).
- On Windows only: The framework directory must be stored in a directory called Frameworks. The executable code (.dll) must be stored in a directory called Executables that has the same parent as the Frameworks directory. If the framework is statically linked into applications, the Executables directory (full path) should be in the PATH environment variable. (On other OPENSTEP platforms, the executable code file is stored within the framework directory, like a bundle.)

How NSBundles Search for Resources

- The algorithm that NSBundles use to find resources has changed somewhat from that of NXBundles, and there are changes to the structure of bundles themselves. A bundle's resources are now stored in a directory named Resources within the bundle directory. Within the Resources directory are the non-localized resources and the localized resource directories (English.lproj, Swedish.lproj, etc., as with NXBundle). The addition of the Resources directory is primarily a way to simplify Framework versioning. Other changes have been made to reduce the amount of computation required to find resources.
-
- Suppose we are searching for the resource with name Main and type nib. The bundle's resource path, the "top level", is searched first, for the file Main.nib. If the file is not found there, each of the language subdirectories are each searched, in the user's preference order. This is a change from NXBundle's behavior, where the language subdirectories were searched first. This change means that the localized version of a resource that also exists at the top level will not be found, but the top level one will be. All non-localized resources should be placed in the top level, and no localized resources should exist at the top level.
-
- When a resource is found, the algorithm checks to see if a resource of the name Main-$(PLATFORM_OS) of type nib exists. $(PLATFORM_OS) represents the make variable of the same name, and takes on the same values that the make variable takes on at compile time. For example, on Windows, during a project build, $(PLATFORM_OS) in the Makefile.postamble will have the value "winnt". When Main.nib is found in a directory, the search algorithm does one final check to see if Main-winnt.nib exists in that same directory. If it does, the search algorithm returns the path to that resource; if it does not, the search algorithm returns the path to Main.nib. Note that for Main-winnt.nib to be found, a file named Main.nib must exist in the same directory; this also applies within each language resource directory. It is expected that a developer will choose one of the platform-specific versions to name without this $(PLATFORM_OS) suffix, and give the other platform-specific versions of the resource extended names. The values that $(PLATFORM_OS) can take on are currently "winnt" (on OPENSTEP for Windows), "nextstep" (on OPENSTEP for MACH), "hpux"(on PDO for HP-UX), and "solaris" (on PDO for Solaris).
-
- Another way to accommodate platform-specific resources is by using the inDirectory: parameter of the resource-searching methods. The inDirectory: parameter is primarily intended to facilitate the collection of resources of a common type or purpose into a single directory; for example, all images could be put into a directory called Images within the resource directory. (Note that the AppKit's +imageNamed: method in NSImage does not support searching arbitrary directories for images.) As such, the inDirectory: parameter can be used to manage platform-specific resources. This is less "automatic" however, and requires the developer to specify the name of the platform-specific directory as well as replicate the required resources and language projects within that directory. The $(PLATFORM_OS) mechanism described above is simpler to use, particularly if the number of platform-specific resources is small.

Using API not in OpenStep

- Many new methods and classes were added for 4.0 and some new methods for 4.1 and 4.2, many outside the purview of the OpenStep specification. To restrict those that are defined to the methods and classes in OpenStep, add the flag -DSTRICT_OPENSTEP to the OTHER_CFLAGS variable in the project's Makefile.preamble.

Foundation Defect and Change List

- This section documents many of the known issues with Foundation in OPENSTEP 4.0, 4.1, and 4.2, and the fixes and changes that have been made in OPENSTEP 4.1 and 4.2. Not all of the issues apply to the current release±refer to the Releases and Disposition fields in each note. Defects not present in the current release are of interest to those developing software on the current release with plans to deploy on a previous release. (However, we do not recommend that developers develop on a version newer than that planned for deployment.)

Issue: NSBundle -localizedStringForKey:value:table: caches default values

Description: NSBundle's -localizedStringForKey:value:table: method incorrectly caches the default value passed as the second parameter if the key isn't found in the table. On subsequent calls with the same key this first default value is returned. Sometimes, however, the default value may need to be different, even with the same key, in different locations in code.

Issue: Extended formatting for NSCalendarDates

Description: The number-formatting sequences for NSCalendarDates (%d, %e, %H, %I, %j, %m, %M, %S, %w, %y, %Y), during the construction of a description, can now contain formatting flags between the `%' and format code, to the extent that the string methods +stringWithFormat:, -appendFormat:, etc. understand them. Format flags are not understood during parsing from a format, however. Note that per 70220 [below], NSDateFormatters use their format string both to display the date and to parse a date from a string (which the user entered in a text field, for example), so this modest extension should not be used in the format string of NSDateFormatters. Setting the date formatter to allow natural language may obviate the issue (but may be undesirable for application reasons)

Issue: NSInvocation always retains the return value

Description: NSInvocation always retains object return values. This can cause issues if the return value of a method is not a fully initialized object. Only +alloc and +allocWithZone: return uninitialized objects, so this is only an issue if a program uses invocations to send either of those methods to a class object. If an application contains its own methods which return objects which are not fully initialized, it should avoid sending those messages with an NSInvocation or over Distributed Objects.

Issue: NSMethodSignature's -getArgumentTypeAtIndex: and -methodReturnType return too much information

Description: These NSMethodSignature methods return a string which contains the type descriptors for the requested argument plus all the type descriptors for the arguments following.

Workaround: Use NSGetSizeAndAlignment() to parse the first type. NSGetSizeAndAlignment() returns the first parameter pointer, advanced to the next type in the type string. Pass the return value of either of those methods as the first parameter to NSGetSizeAndAlignment() and pass NULL for the second and third parameters (or pass pointers to unsigned integers if either of those values is interesting); record the return value of that function in another variable. The difference between the return value and the first parameter is the length of the first type in the first parameter to NSGetSizeAndAlignment(). The single type string can then be strncpy()'d into its own buffer.

Issue: Collections that contain themselves don't unarchive well

Description: Unarchiving an object graph with a collection which contains itself, or contains an object which archived a reference to the collection, may cause a program either to crash immediately when the archiving system attempts to retain it, or to crash later when a freed object is sent a message. The issue here is that the collection gets retained when the recursive reference is unarchived (which is normal) before it has completed its initialization in -initWithCoder:, which can be an issue for objects which keep track of their own retain count (as the collection classes do).

Issue: NSConnection doesn't let go on NSRunLoop when it has nothing to do

Description: NSConnections do not register/un-register their ports with the run loop lazily, as they have something to serve. Specifically, an NSConnection with no root object and no local objects vended over the wire (no local proxies) should not have its ports registered with a run loop, since it can never receive any messages. This causes code like the following to never terminate:

id server = [NSConnection rootProxyForConnectionWithRegisteredName:@"name" host:@"*"];

... do stuff with server ...

[server release];

... do stuff which adds a one-shot timer to the current run loop ...

Issue: Proxies cannot be notification observers unless they are retained

Description: Because NSNotificationCenter does not retain observers, registering an observer with a remote NSNotificationCenter (the observer would be a proxy in the remote process) will eventually cause a crash of the remote process when it tries to message a freed object, unless the remote process explicitly retains the proxy. This situation is a bit arcane, but the same type of issue can happen with other objects that don't retain objects that they know about.

Workaround: Use an explicit protocol to tell the server (the process vending the notification center) to register and unregister an observer. The server then retains and registers the observer with the vended notification center, and unregisters and releases the observer when the client tells it to do so. (If an unregister mechanism is not part of the protocol, and used, the object will never be released.)

Issue: Changed defaults don't appear sometimes to have taken affect

Description: The default NSUserDefaults domain search order places the NSArgumentDomain before the application's domain. This is usually desirable for reading defaults, but may not be if you set/change default values. If you set a value for a default that was passed as an option on the command-line, the value is correctly set/changed in the application's domain, but -objectForKey: will still return the value found in the NSArgumentDomain, because by default it is searched first.

Workaround: There are various workarounds depending upon the application and its use of user defaults. The following options are relative to a particular NSUserDefaults instance (that is, if you create multiple user defaults instances, you'd have to do the workaround for each individually).

1. Remove the NSArgumentDomain from the search list, perhaps after adding any keys it contains to the registration domain; command-line specified defaults will not be found, or not have priority over same-keyed defaults in the application's domain, however.

2. Move the NSArgumentDomain after the application's domain; command-line specified defaults will not have priority over same-keyed defaults in the application's domain, however.

3. Each time you set a default value, set it in the argument domain (difficult and not worth the trouble).

4. Best solution: Create a subclass of NSUserDefaults. For each defaults instance created, create a new volatile domain, tell the instance about it (-setVolatileDomain:forName:) perhaps calling it "ChangedDefaults" (don't give it a name beginning with "NS"!), and insert it first in the domain search list of the new defaults instance. Override the -setObject:forKey: and -removeObjectForKey: methods to set/remove the value in the "ChangedDefaults" volatile domain, and then call [super ...] to do the same for the application domain. The following code illustrates what these override methods might look like:

```
- (void)setObject:(id)value forKey:(NSString *)defaultName {
NSDictionary *changedDomain;
id oldValue;
```

```
[super setObject:value forKey:defaultName];
changedDomain = [self volatileDomainForName:@"ChangedDefaults"];
oldValue = [changedDomain objectForKey:defaultName];
if (![oldValue isEqual:value]) { // Something to do
NSMutableDictionary *newDomain;
newDomain = [[NSMutableDictionary allocWithZone:[self zone]]
initWithDictionary:changedDomain];
[newDomain setObject:value forKey:defaultName];
[self setVolatileDomain:newDomain forName:@"ChangedDefaults"];
[newDomain release];
}
}

- (void)removeObjectForKey:(NSString *)defaultName {
NSDictionary *changedDomain;
id oldValue;
[super removeObjectForKey:defaultName];
changedDomain = [self volatileDomainForName:@"ChangedDefaults"];
oldValue = [changedDomain objectForKey:defaultName];
if (oldValue) { // Something to do
NSMutableDictionary *newDomain;
newDomain = [[NSMutableDictionary allocWithZone:[self zone]]
initWithDictionary:changedDomain];
[newDomain removeObjectForKey:defaultName];
[self setVolatileDomain:newDomain forName:@"ChangedDefaults"];

Issue: Files mapped with -initWithContentsOfMappedFile: cannot be removed

Description: On Windows, you cannot remove a file that a process has mapped; this is a feature of the operating system. However, even after an NSData initialized with -initWithContentsOfMappedFile: is deallocated, a program may not be able to immediately remove the file. Issue: NSUserDefaults does not reflect Windows Registry case semantics

Description: The Windows Registry is case-preserving but case-insensitive with respect to keys (registry keys, not default keys). NSUserDefaults

doesn't reflect this in its behavior, so, for example, if a persistent domain "MyApp" exists, and a persistent domain "MYAPP" is created, the new domain will eradicate the existing one and all defaults in the existing one will be lost. This does not affect default keys or values, only domain names.

Issue: D.O. and archiving type signature checks don't take structure tags into account

Description: The NeXT compiler does not include structure names in type encoding strings produced from typedefs of structures (for example, @encode(NSRange)); instead, the structure tag is given as "?". This is a bug in the compiler, but one that cannot be fixed for backwards compatibility reasons. To achieve compatibility with SunSoft's compiler (which correctly emits all structure tags), a "?" as a structure tag now acts as a "wildcard", matching anything. This is unlikely to affect user applications, but developers who construct their own type encoding strings should note this, as 4.1 is more permissive than OPENSTEP 4.0 was, a possible backwards-deployment issue.

Issue: Incorrect behavior when copying NSMutableDictionarys

Description: According to the OpenStep specification, when you send -copy or -copyWithZone: to an NSMutableDictionary you should get back a deep immutable copy. This was the behavior implemented in OPENSTEP 4.0. However, in OPENSTEP 4.1 (all platforms) what you get back is a shallow immutable copy--the objects in the dictionary are merely retained instead of being copied.

This change in behavior can have subtle effects within any code that copies NSMutableDictionarys. For example, suppose you have a mutable dictionary populated with objects, and you create a copy (which should be a deep immutable copy). If you then modify one of the objects that you had put into the original dictionary, the modified object will appear in the copy of the dictionary as well as in the original. This bug means that a copy of a dictionary can change out from under you unexpectedly. In an application, you might see no change, incorrect operation, or a crash as a result. Because it doesn't always crash your applications, and because it manifests itself in a number of different ways, this bug can be particularly difficult to detect.

Workaround: While you may not be able to alter the way that libraries you link against are written, in your own code you can work around this bug simply by avoiding the use of either -copy or -copyWithZone: with NSMutableDictionarys. The easiest way to do this is to use the undocumented (in 4.1) -initWithDictionary:copyItems: method, as shown here:

[[NSDictionary allocWithZone:NULL] initWithDictionary:dict copyItems:YES]

This method only makes sense when you know you have a dictionary object, but that's often the case (-isKindOfClass: can be used for testing this). Note that -initWithDictionary:copyItems: isn't part of the OpenStep specification.

N is any integer N >= 2,

M is the maximum number of pools there have ever been at any instant, up to that point, and

P = { 0 if M <= 16; ceil(M - 13) / 4) if M > 16 }

2. the top pool grows to be large (having more than 4096 objects in it), and is then released

Upon the next autorelease, the autorelease pool will shrink its storage, shrinking it to exactly the amount required for the (2019 - 4 * P + 2048 * N) objects in the remaining pools, and then try to add the newly autoreleased object one slot past the end of the new storage. The shrink in this case is not taking into account the extra storage that will immediately be needed.

Issue: Issues with NSDecimalNumber addition and subtraction

Description: When two NSDecimalNumber objects have a large difference in their precision (for example, 1070464.1 and 10458008.858880000582251216050000055879), the numbers can be added or subtracted incorrectly.

Issue: NSValues and NSNumbers in 3.3 archives can't be unarchived

Description: In the 3.3 Foundation, NSValues and NSNumbers were archived in such a way that a helper class, NSValueDecoder, was needed to unarchive them. This class does not exist in the Foundation in 4.0 or 4.1, so such archives cannot be read in.

Issue: Date parsing not handling 1-digit numbers well

Description: If an application parsed the string "96/5" with the format "%y/%m", the application would raise an out-of-bounds exception. If the string was "96/05", things worked fine.

Issue: NSArray methods not working with fault parameters

Description: The NSArray methods -indexOfObject:, -indexOfObject:inRange:, and -containsObject: cause a raise of a selector-not-recognized exception when the first parameter is a faulted object. The -firstObjectCommonWithArray: has the same issue when the array parameter is an array of faults.

Issue: NSFileManager methods don't work on strict 8.3 DOS file systems

Description: The NSFileManager methods -createFileAtPath:contents:attributes: and -movePath:toPath:handler: can fail on FAT file systems which are strict about 8.3 file names, such as available on Mach. The FAT file systems of Windows NT and Windows 95 are more forgiving.

Issue: Local proxies not immediately released when remote proxy released

Description: For performance reasons, Distributed Objects batches, on the remote side, release methods destined for local proxies. Whenever a synchronous method (i.e., non-oneway) is sent to a remote object, all pending releases on local objects are returned with the return value of the method (which may be void of course). Since the local proxy retains the object it represents (part of its function is to make sure the local object which has been vended remains valid at least as long as there is an outstanding remote proxy for it), a local object which has been vended over the wire, but released on the server side, will persist until the client sends a synchronous message to the server. If a client and server communicate only with oneway messages, local objects which are sent remotely by proxy (as a parameter for example) will persist "forever", or until the local connection is invalidated. This can be an issue for long-lived clients which maintain a persistent connection to a server.
